This connector is for connecting the controller (such as a PC) with the GP-IB cable. For information on how to connect the GP-IB cable, refer to the following page.

1.2 Connection via the GP-IB Interface

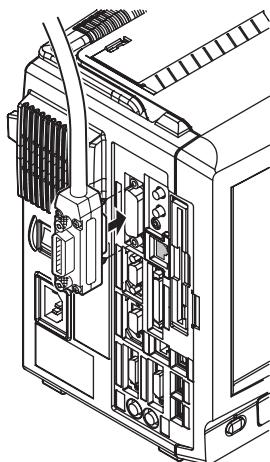

1.2 Connection via the GP-IB Interface

GP-IB Cable

The GP-IB connector on the side panel of the DL750/DL750P is a 24-pin connector that conforms to IEEE Standard 488-1978. Use a GP-IB cable that also conforms to IEEE Standard 488-1978.

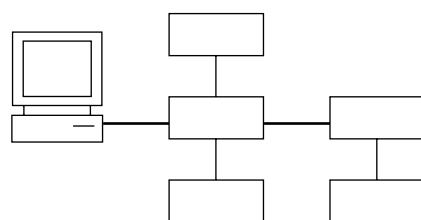

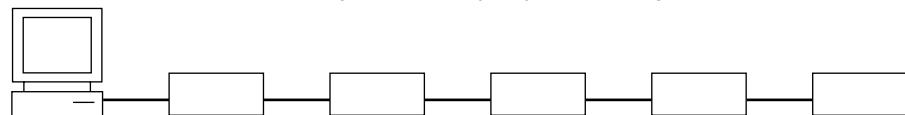

Connection Method

Connect the GP-IB cable as shown below.

Connection Precautions

- Be sure to tighten the screws on the GP-IB cable connector firmly.
- The instrument can be connected to more than one item of equipment (e.g. a personal computer) if more than one GP-IB cable is used. However, it is not possible to connect more than 15 items of equipment (including the controller) to a single bus.
- If you connect the instrument to more than one item of equipment, make sure that a different address is used for each item.
- Each connecting cable must be 2 m or less in length.
- The total length of all the cables must not exceed 20 m.
- While communications are in progress, more than two-thirds of the connected equipment items must be turned ON.
- When connecting more than one item of equipment, connect them so that the connection route forms a star or linear configuration. Loop or parallel wiring is not allowed.

CAUTION

Be sure to switch off power to both your PC and the oscilloscope before connecting or disconnecting cables. Failure to switch power off may cause internal circuit failure or improper operation.

1.3 GP-IB Interface Functions

GP-IB Interface Functions

Listener Function

- Allows you to make the settings which you can make using the panel keys on the instrument, except for the power ON/OFF and GP-IB communications settings.
- Receives commands from a controller requesting output of set-up and waveform data.
- Also receives status report commands

Talker Function

Outputs set-up and waveform data.

Note

The listen-only, talk-only and controller functions are not available on this instrument.

Switching between Remote and Local Mode

When Switched from Local to Remote Mode

Remote mode is activated when a REN (Remote Enable) message is received from a controller while local mode is active.

- REMOTE is displayed on the upper right of the screen.
- All front panel keys except **SHIFT+CLEAR TRACE** can no longer be operated any more.
- Settings entered in local mode are retained.

When Switched from Remote to Local Mode

Pressing **SHIFT+CLEAR TRACE** in remote mode puts the instrument in local mode. However, this is not possible if Local Lockout has been set by the controller (page 1-7).

- The REMOTE indicator on the upper right of the screen is turned off.
- All front panel keys are operative.
- Settings entered in remote mode are retained.

Note

The GP-IB interface cannot be used simultaneously with other communications interfaces (serial (RS-232), USB, or network).

1.5 Setting up this Instrument (GP-IB)

1.5 Setting up this Instrument (GP-IB)

Operating Procedure

Selecting the Communication Interface

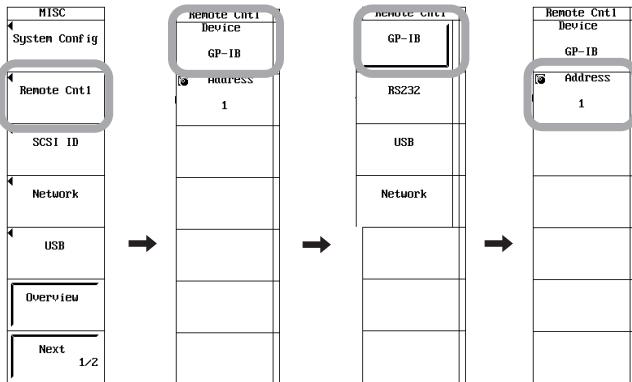

1. Press **MISC**.
2. Press the **Remote Cntl** soft key.
3. Press the **Device** soft key to select GP-IB.

Note

Only the communications interfaces selected under Device are available. If commands are sent using an unselected communications interface, the command will not be received.

Setting the Address

4. Turn the **jog shuttle** to set the desired address.

Explanation

When you make settings which can be made using the front panel keys of the instrument or when you output setup data or waveform data using the controller, the following settings must be made.

Setting the Address

This function allows you to set the instrument's address for addressable mode within the range of 0 to 30. Each item of equipment connected via a GP-IB interface has its own address, by which it can be identified. Care must be taken to ensure that all interconnected devices are assigned unique addresses.

Note

Do not change the address while the GP-IB interface is being used by the controller.

1.6 Response to Interface Messages

Response to Interface Messages

Response to a Uni-line Message

IFC(Interface Clear)

Clears the talker and listener. Stops output if data is being output.

REN(Remote Enable)

Switches between remote and local modes.

IDY (Identify) is not supported.

Response to a Multi-Line Message (Address Command)

GTL(Go To Local)

Switches to local mode.

SDC(Selected Device Clear)

Clears the program message (command) which is currently being output. Also clears the output queue (page 7-5).

*OPC and *OPC? will be disabled if they are currently being executed.

*WAI and :COMMUnicatE:WAIT will be stopped immediately.

PPC (Parallel Poll Configure), GET (Group Execute Trigger) and TCT (Take Control) are not supported.

Response to a Multi-Line Message (Universal Command)

LLO(Local Lockout)

Invalidates SHIFT+CLEAR on the front panel to disable switching to local mode.

DCL(Device Clear)

Same as SDC.

SPE(Serial Poll Enable)

Sets the talker function to serial poll mode for all equipment connected to the communications bus. The controller performs polling on equipment sequentially.

SPD(Serial Poll Disable)

Clears serial poll mode as the talker function for all equipment connected to the communications bus.

PPU (Parallel Poll Unconfigure) is not supported.

What is an Interface Message?

An interface message is also called an interface command or bus command, and is issued by the controller. Interface messages are classified as follows.

Uni-Line Messages

Messages are transferred through a single control line. The following three types of uni-line message are available.

IFC (InterFace Clear)

REN (Remote ENable)

IDY (IDentifY)

1.6 Response to Interface Messages

Multi-Line Message

Eight data lines are used to transmit a message. Multi-line messages are classified as follows.

Address Commands

Valid when the equipment is designated as a listener or a talker. The following five address commands are available.

- **Commands valid for equipment designated as a listener;**

GTL (Go To Local)
SDC (Selected Device Clear)
PPC (Parallel Poll Configure)
GET (Group Execute Trigger)

- **Command valid for equipment designated as a talker;**

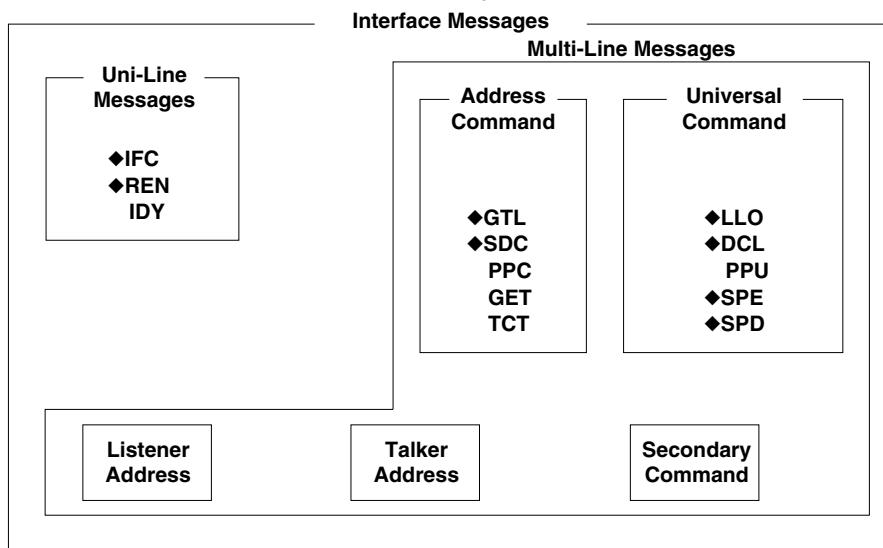

TCT (Take ConTrol)

Universal Commands

Valid for any item of equipment, irrespective of whether the item is designated as a listener or a talker. The following five universal commands are available.

LLO (Local LockOut)
DCL (Device CLear)
PPU(Parallel Poll Unconfigure)
SPE (Serial Poll Enable)
SPD (Serial Poll Disable)

In addition to the above commands, a listener address, talker address on secondary command can be sent in an interface message.

Messages marked with a “◆” are interface messages supported by the DL750/DL750P.

Note

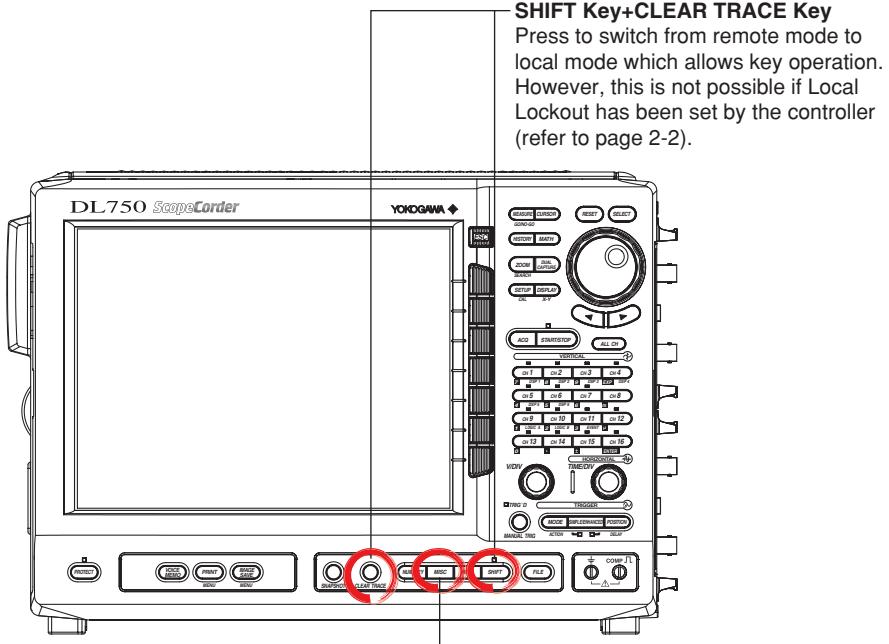

Differences between SDC and DCL

The SDC command is an address command and requires that both the talker and listener be designated; however DCL is a universal command and does not require that the talker and listener be designated. Therefore, SDC is used for particular items of equipment, while DCL can be used for any equipment connected to the communications bus.

2.4 Handshaking

To use an serial (RS-232) interface for transferring data between this instrument and a computer, it is necessary to use certain procedures by mutual agreement to ensure the proper transfer of data. These procedures are called "handshaking." Various handshaking systems are available depending on the computer to be used; the same handshaking system must be used for both the computer and this instrument. This instrument allows you to choose any handshaking mode from the following three modes.

Handshake Format Descriptions→○

| Handshake Method | Data Sending Control (Control Method When Sending Data to a Computer) | | | Data Receiving Control (Control Method When Receiving Data from a Computer) | | |
|-----------------------------|---|--|--------------|--|---|--------------|
| | Software Handshake | Hardware Handshake | No handshake | Software Handshake | Hardware Handshake | No handshake |
| The Menu of this Instrument | Sending stops when X-off is received, and sending is resumed when X-on is received. | Sending stops when CB(CTS) is False, and sending is resumed when CB is True. | | X-off is sent when received data buffer becomes 3/4-full, and X-on is sent when the received data buffer is only 1/4-full. | CA (RTS) is set to False when received data buffer is only 3/4-full, and is set to True when received data buffer is only 1/4-full. | |
| OFF-OFF | NO-NO | | ○ | | | ○ |
| XON-XON | XON-XON | ○ | | ○ | | |
| CS-RS | CTS-RTS | | ○ | | ○ | |

OFF-OFF

Transmission Data Control

There is no handshake status between the instrument and host computer. The X-OFF and X-ON signal from the host computer is processed as data, and the CS signal is ignored.

Reception Data Control

There is no handshake status between the recorder and host computer. When the recorder reception buffer becomes full, the excess data is discarded. RS = True (fixed).

XON-XON

Transmission Data Control

A software handshake status is established between the instrument and host computer. The instrument will stop a data transmission when an X-OFF signal is received from the host computer, and will resume transmission when the next X-ON signal is received. A CS signal from the host computer is ignored.

Reception Data Control

A software handshake status is established between the instrument and host computer. When the instruments reception buffer vacancy reaches 64 bytes, the X-OFF signal will be sent to the host computer. When the reception buffer vacancy reaches 192 bytes, the X-ON signal will be sent. RS = True (fixed).

CS-RS

Transmission Data Control

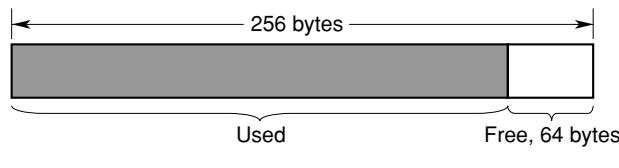

A software handshake status is established between the instrument and host computer. The instrument will stop a data transmission if a “CS = False” status is established, and will resume the transmission when a “CS = True” status is established. The X-OFF and X-ON signals from the host computer are processed as data.

Reception Data Control

A hardware handshake status is established between the instrument and host computer. When the instruments reception buffer vacancy reaches 64 bytes, an “RS=False” status will be established. When the reception buffer vacancy reaches 192 bytes, an “RS=True” status will be established.

Precautions Regarding Data Receiving Control

When handshaking is used to control the reception of data, data may still be sent from the computer even if the free space in the receive buffer drops below 64 bytes. In this case, after the receive buffer becomes full, the excess data will be lost, whether handshaking is in effect or not. Data storage to the buffer will begin again when there is free space in the buffer.

When handshaking is in use, reception of data will stop when the free space in the buffer drops to 64 bytes since data cannot be passed to the main program fast enough to keep up with the transmission.

After reception of data stops, data continues to be passed to the internal program. Reception of data starts again when the free space in the buffer increases to 192 bytes.

Whether handshaking is in use or not, if the buffer becomes full, any additional data received is no longer stored and is lost.

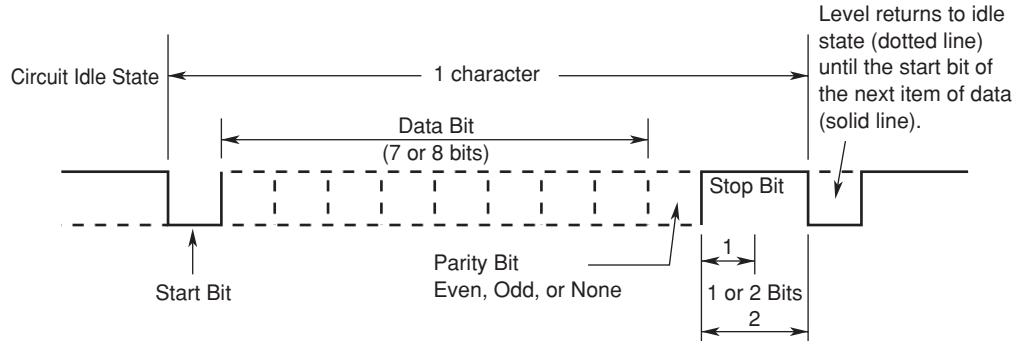

Data Receiving Control Using Handshaking

Note

It is necessary to create a host computer program which prevents the buffers of both the instrument and the computer from becoming full.

2.5 Matching the Data Format

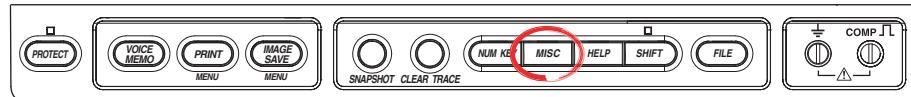

The serial (RS-232) interface of this instrument performs communications using start-stop synchronization. In start-stop synchronization, one character is transmitted at a time. Each character consists of a start bit, data bits, a parity bit, and a stop bit. Refer to the figure below.

Switching between Remote and Local Mode

When Switching from Local to Remote Mode

If the DL750/DL750P receives a ":COMMUnicate:REMote ON" command from the PC when it is in the local mode, it switches to the remote mode.

- REMOTE is displayed at the lower left corner of the screen.
- All keys except **SHIFT+CLEAR TRACE** are disabled.
- The settings that existed in the local mode are maintained even when the DL750/DL750P switches to the remote mode.

When Switching from Remote to Local Mode

Pressing **SHIFT+CLEAR TRACE** when the instrument is in the remote mode causes the instrument to switch to the local mode. However, this is void when the DL750/DL750P has received a ":COMMUnicate:LOCKout ON" command from the PC (local lockout condition). When the DL750/DL750P receives a ":COMMUnicate:REMote OFF" command from the PC, the DL750/DL750P switches to the local mode regardless of the local lock condition.

- REMOTE indication at the lower right corner disappears.
- Key operations are enabled.
- The settings that existed in the remote mode are maintained even when the instrument switches to the local mode.

Note

The USB interface cannot be used simultaneously with other communications interface (GP-IB, serial (RS-232), or network).

3.3 Connection via the USB Interface

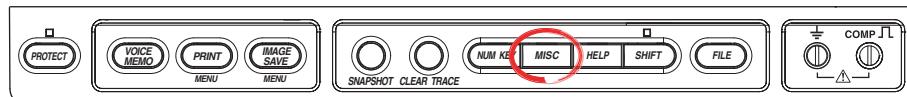

Connection Precautions

- Connect the USB cable by inserting the connector firmly into the USB connector.
- When connecting multiple devices using USB hubs, connect the DL750/DL750P to the USB hub that is closest to the controller.
- Do not mistakenly insert the USB cable to the GO/NO-GO output terminal. This may cause damage to the DL750/DL750P.
- Do not connect or disconnect the USB cable after the power is turned ON until the DL750/DL750P boots up completely (until the DL750/DL750P is ready for operation, approximately 20 to 30 s). Doing so can cause damage to the DL750/DL750P.

3.4 Setting up this Instrument (USB)

3.4 Setting up this Instrument (USB)

Operating Procedure

Selecting the Communication Interface

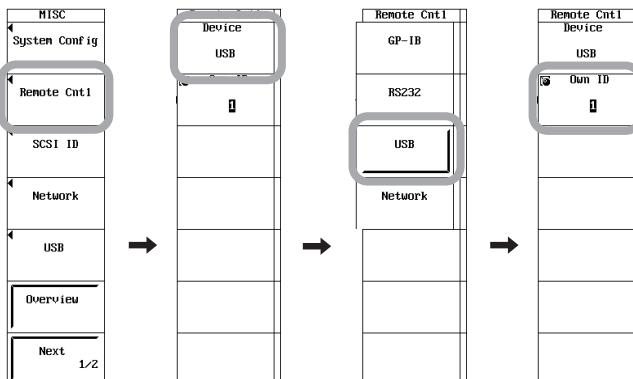

1. Press **MISC**.
2. Press the **Remote Cntl** soft key.
3. Press the **Device** soft key to select USB.

Note

Only the communications interfaces selected under Device are available. If commands are sent using an unselected communications interface, the command will not be received.

Setting the ID Value

4. Turn the **jog shuttle** to set the ID value.

Explanation

Carry out the following settings when using a controller to set information that can be specified through key operation on the DL750/DL750P or when outputting setup data or output waveform data to the controller.

Setting the ID Value

Set the ID value of the DL750/DL750P within the following range:

1 to 127

You can connect multiple devices to a controller using the USB interface. If multiple devices are connected in a single USB system, the ID value is used by the controller to identify each device. Therefore, unique ID values must be assigned to the devices within a single system.

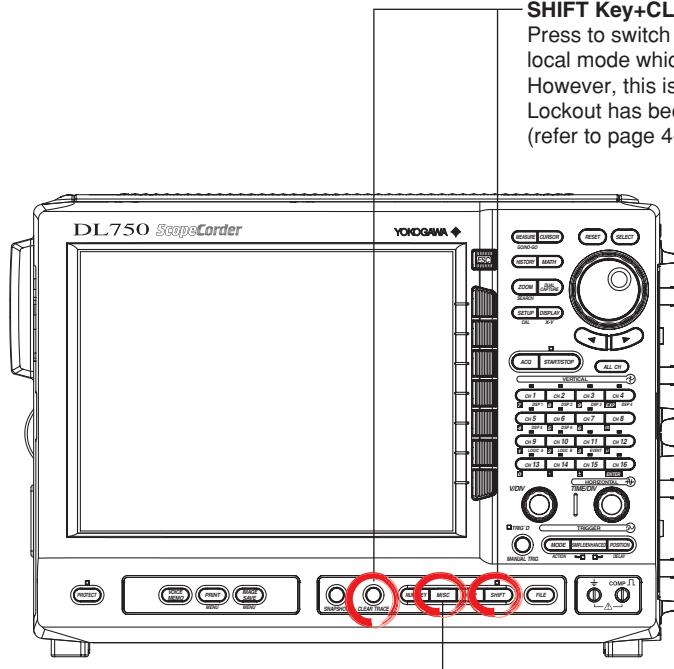

Note

Do not change the ID value while using the USB.

Switching between Remote and Local Mode

When Switched from Local to Remote

Remote mode is activated when the ":COMMUnicate:REMote ON" command is received from a controller while local mode is active.

- REMOTE is displayed on the upper right of the screen.
- All front panel keys except **SHIFT +CLEAR TRACE** can no longer be operated.
- Settings entered in local mode are retained even when switching to remote mode.

When Switched from Remote to Local Mode

Pressing **SHIFT +CLEAR TRACE** in remote mode puts the instrument in local mode. However, this is not possible when the ":COMMUnicate:REMote ON" command is received from the controller while Local Lockout mode is active. Local mode is activated when the ":COMMUnicate:REMote OFF" command is received regardless of Local Lockout.

- The REMOTE indicator on the upper right of the screen is turned off.
- All front panel keys are operative.
- Settings entered in remote mode are retained even when switching to local mode.

Note

The network interface cannot be used simultaneously with other communications interfaces (GP-IB, serial (RS-232), or USB).

User Verification Function

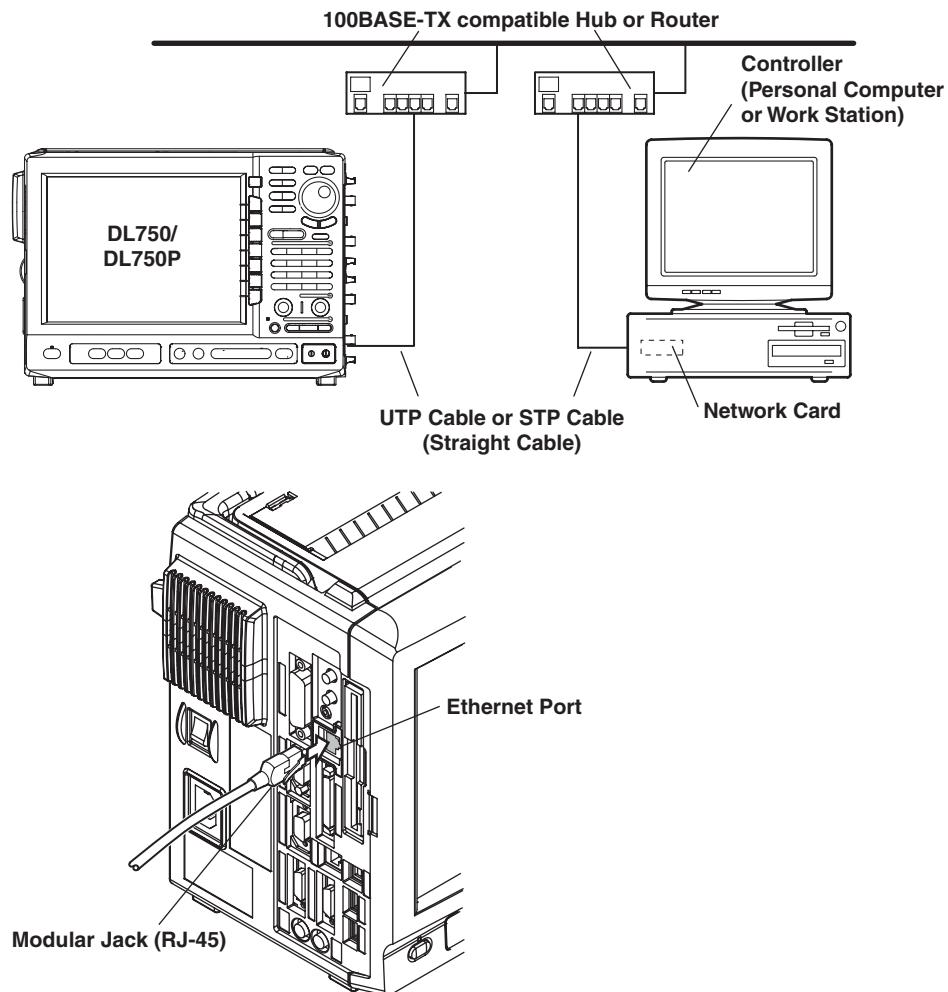

The user must enter a user name and password for the interface when connecting to the network. The user name and password is set on the instrument in the Remote Cntl setting screen under the MISC menu. For details, see section 4.4, "Setting up this Instrument (Network)."

4.3 Connection via the Network Interface

4.3 Connection via the Network Interface

Connection Method

Connect a UTP (Unshielded Twisted-Pair) or STP (Shielded Twisted-Pair) cable that has been connected to a hub to the 100BASE-TX port on the rear panel of the unit.

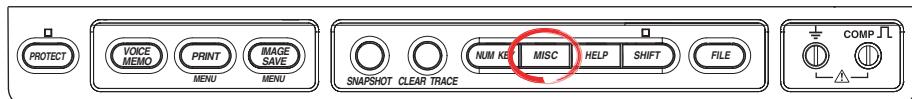

Connection Precautions

- You must use a straight cable when connecting the unit to a controller or a work station. We cannot guarantee results using a cross cable.
- When using a UTP cable (straight cable), be sure to use only a category 5 cable.

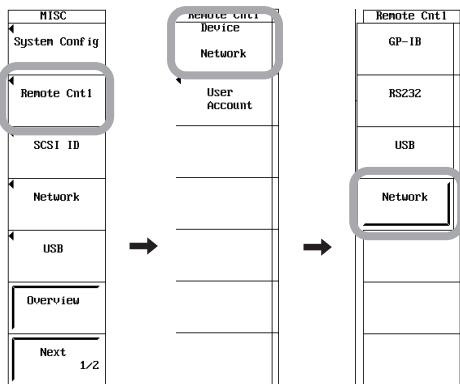

4.4 Setting up this Instrument (Network)

Operating Procedure

TCP/IP Settings

The following TCP/IP settings must be entered in order to use the network interface functions.

- IP Address
- Subnet Mask
- Default Gateway

For details about how to enter these settings, see section 16.2, "Setting up the TCP/IP" in user's manual IM701210-06E.

Description

Use the settings below to setup communications so that you can input settings on the instrument using the controller, or output settings or values to the controller.

Setting the User Name and Password

There is a user verification function for the Network interface. The user name and password are set on the instrument ahead of time.

- **User Name Setting**

15 characters or less may be used. The default value is anonymous.

- **Password Setting**

15 characters or less may be used.

Setting the Timeout Time

If the unit is not being accessed at the specified timeout time, the connection to the network will be automatically closed.

TCP/IP Settings

For details, see section 16.2, "Setting up the TCP/IP" in user's manual IM701210-06E.

Note

- If a user verification error occurs, the connection to the instrument is cut.
 - If the login name is anonymous, it is not necessary to enter a password.
 - When changing the user name, password, timeout time, or TCP/IP settings, the settings will not take effect until the unit is turned OFF then back ON again.

Chapter 5 Before Programming

5.1 Messages

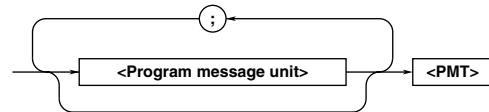

Messages

Blocks of message data are transferred between the controller and this instrument during communications. Messages sent from the controller to this instrument are called program messages, and messages sent back from this instrument to the controller are called response messages.

If a program message contains a query command, i.e. a command which requests a response, this instrument returns a response message. A single response message is always returned in reply to a program message.

Program Messages

The format of a program message is shown below.

<Program Message Unit>

A program message consists of one or more program message units; each unit corresponds to one command. This instrument executes commands one by one according to the order in which they are received.

Program message units are delimited by a " ; ." For a description of the format of the program message unit, refer to the explanation given further below.

Example : ACQuire:MODE NORMAL; COUNT 1<PMT>

Unit Unit

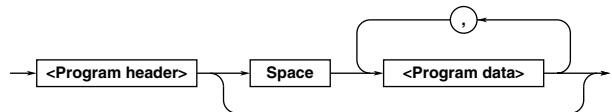

<PMT>

PMT is a terminator used to terminate each program message. The following three types of terminator are available.

- NL (New Line) : Same as LF (Line Feed). ASCII code " 0AH " is used.
- ^END : END message defined in IEEE488.1. (EOI signal)
(The data byte sent with an END message will be the final item of the program message unit.)
- NL^END : NL with an END message attached (NL is not included in the program message unit.)

Program Message Unit Format

The format of a program message unit is shown below.

<Program Header>

A program header is used to indicate the command type. For details, refer to page 5-3.

<Program Data>

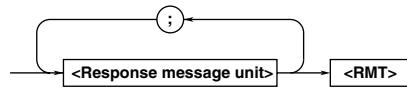

If certain conditions are required for the execution of a command, program data must be added. Program data must be separated from the header by a space (ASCII code " 20H "). If multiple items of program data are included, they must be separated by a " , " (comma). For details, refer to page 5-5.

Example : ACQuire:MODE NORMAL<PMT>

Header Data

Response Messages

The format of a response message is shown below.

<Response Message Units>

A response message consists of one or more response message units: each response message unit corresponds to one response.

Response message units are delimited by a " ; ." For the response message format, refer to the next page.

Example : ACQuire:MODE NORMAL; COUNT 1<RMT>

Unit Unit

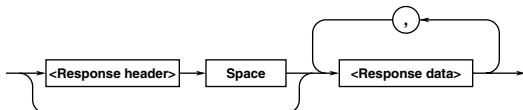

<RMT>

RMT is the terminator used for every response message. Only one type of response message is available; NL^END.

5.1 Messages

Response Message Unit Format

The format of a program message unit is shown below.

<Response Header>

A response header sometimes precedes the response data. Response data must be separated from the header by a space. For details, refer to page 5-4.

<Response Data>

Response data is used to define a response. If multiple items of response data are used, they must be separated by a ", " (comma). For details, refer to page 5-5.

Example

1.25E-02<RMT> :ACQUIRE:MODE NORMAL<RMT>
Data Header Data

If a program message contains more than one query, responses are made in the same order as the queries. Normally, each query returns only one response message unit, but there are some queries which return more than one response message unit. The first response message unit always responds to the first query, but it is not always true that the 'n' th unit always responds to the 'n' th query. Therefore, if you want to make sure that a response is made to each query, the program message must be divided up into individual messages.

Points to Note Concerning Message Transmission

- It is always possible to send a program message if the previous message which was sent did not contain any queries.
- If the previous message contained a query, it is not possible to send another program message until a response message has been received. An error will occur if a program message is sent before a response message has been received in its entirety. A response message which has not been received will be discarded.
- If an attempt is made by the controller to receive a response message, even if there is no response message, an error will occur. An error will also occur if the controller makes an attempt to receive a response message before transmission of a program message has been completed.
- If a program message of more than one unit is sent and some of the units are incomplete, this instrument receives program message units which the instrument thinks complete and attempts to execute them. However, these attempts may not always be successful and a response may not always be returned, even if the program message contains queries.

Dead Lock

This instrument has a buffer memory in which both program and response messages of 1024 bytes or more can be stored. (The number of bytes available will vary depending on the operating state of the instrument.) If both buffer memories become full at the same time, this instrument becomes inoperative. This state is called deadlock. In this case, operation can be resumed by discarding the response message.

No dead lock will occur, if the size of the program message including the PMT is kept below 1024 bytes. Furthermore, no deadlock will occur if the program message does not contain a query.

5.2 Commands

Commands

There are three types of command (program header) which can be sent from the controller to this instrument. They differ in the format of their program headers.

Common Command Header

Commands defined in IEEE 488.2-1987 are called common commands. The header format of a common command is shown below. An asterisk (*) must always be attached to the beginning of a command.

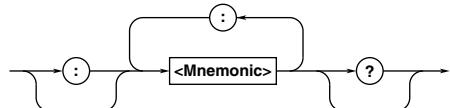

An example of a common command

*CLS

Compound Header

Commands designed to be used only with this instrument are classified and arranged in a hierarchy according to their function. The format of a compound header is illustrated below. A colon (:) must be used when specifying a lower-level header.

An example of a compound header

:ACQuire:MODE

Simple Header

These commands (headers) are functionally independent of each other and are not arranged hierarchically. The format of a simple header is shown below.

An example of a simple header

:START

Note

A mnemonic is a character string made up of alphanumeric characters.

When Concatenating Commands

Command Group

A command group is a group of commands which have the same compound header. A command group may contain sub-groups.

Example Commands relating to acquisition settings

```
:ACQuire:AVERage:COUNT
:ACQuire:MODE
:ACQuire:AVERage:EWEight
:ACQuire:CLOCK
:ACQuire:RLENgth
:ACQuire:COUNT
```

When Concatenating Commands of the Same Group

This instrument stores the hierarchical level of the command which is currently being executed, and performs analysis on the assumption that the next command to be sent will also belong to the same level. Therefore, it is possible to omit the header if the commands belong to the same group.

Example :ACQuire:MODE NORMAL;COUNT 1<PMT>

When Concatenating Commands of Different Groups

A colon (:) must be included before the header of a command, if the command does not belong to the same group as the preceding command. It is impossible to omit a colon (:).

Example :ACQuire:MODE NORMAL;:DISPLAY:
FORMAT SINGLE<PMT>

When Concatenating Simple Headers

When you type in a simple header after another command, you must include a colon (:) before the simple header. It is impossible to omit a colon (:).

Example :ACQuire:MODE NORMAL;:START<PMT>

When Concatenating Common Commands

Common commands defined in IEEE 488.2-1992 are independent of hierarchical level. Thus, it is not necessary to add a colon (:) before a common command.

Example :ACQuire:MODE NORMAL;*CLS;
COUNT 1<PMT>

When Separating Commands with <PMT>

If a terminator is used to separate two commands, each command is a separate message. Therefore, the common header must be typed in for each command even when commands of the same command group are being concatenated.

Example :ACQuire:MODE
NORMAL<PMT>:ACQuire:COUNT 1<PMT>

Upper-level Query

An upper-level query is a compound header to which a question mark is appended. Execution of an upper-level query allows all a group's settings to be output at once. Some query groups comprising more than three hierarchical levels can output all their lower level settings.

Example :CHANnel1?<PMT> -> :CHANNEL1:
DISPLAY ON;LABEL "CH1";
COUPLING DC;POSITION 0.00;
PROBE 10;VDIV 50.0E+00;
BWIDTH FULL;OFFSET 0.0E+00;LSCALE:
MODE 0

In reply to a query, a response can be returned as a program message to this instrument. Transmitting a response can restore the settings made when the query was executed. However, some upper-level queries will not return set-up data which is not currently in use. Note that not all a group's information will necessarily be sent out as a response.

Header Interpretation Rules

This instrument interprets the header received according to the following rules.

- Mnemonics are not case sensitive.
Example "CURSor" can also be written as "cursor" or "Cursor."
 - The lower-case part of a header can be omitted.
Example "CURSor" can also be written as "CURSO" or "CURS."
 - If the header ends with a question mark, the command is a query. It is not possible to omit the question mark.
Example "CURSOR?" cannot be abbreviated to anything shorter than "CURS?."
 - If the "x" at the end of a mnemonic is omitted, it is assumed to be "1."
Example If "CHANnel<x>" is written as "CHAN," this represents "CHANnel1."
 - Any part of a command enclosed by [] can be omitted.
Example "TRIGger[:SIMPLle]:LEVel" can be written as "TRIG:LEV."
- However, a part enclosed by [] cannot be omitted if it is located at the end of an upper-level query.
- Example "TRIGger?" and "TRIGger:SIMPLe?" belong to different upper-level query levels.

5.3 Response

Response

On receiving a query from the controller, this instrument returns a response message to the controller. A response message is sent in one of the following two forms.

- Response Consisting of a Header and Data
If the query can be used as a program message without any change, a command header is attached to the query, which is then returned.
Example :ACQUire:MODE?<PMT> ->
:ACQUire:MODE NORMAL<RMT>
- Response Consisting of Data Only
If the query cannot be used as a program message unless changes are made to it (i.e. it is a query-only command), no header is attached and only the data is returned. Some query-only commands can be returned after a header is attached to them.
Example :MEASure:CHANnel1:PTOPeak:
VALue?<PMT> -> 10.0E+00<RMT>

When Returning a Response without a Header

It is possible to remove the header from a response consisting of a header and data. The "COMMUnicatE:HEADer" command is used to do this.

Abbreviated Form

Normally, the lower-case part is removed from a response header before the response is returned to the controller. Naturally, the full form of the header can also be used. For this, the "COMMUnicatE:VERBose" command is used. The part enclosed by [] is also omitted in the abbreviated form.

5.4 Data

Data

A data section comes after the header. A space must be included between the header and the data. The data contains conditions and values. Data is classified as below.

| Data | Description |
|-------------------------|---|
| <Decimal> | Value expressed as a decimal number (Example: Type of probe of CH2 -> CHANnel2:PROBe 100) |
| <Voltage><Current> | Physical value |
| <Time><Frequency> | (Example: Time axis range -> TIMebase:TDIV 1US) |
| <Register> | Register value expressed as either binary, octal, decimal or hexadecimal (Example: Extended event register value -> STATUS:EESE #HFE) |
| <Character data> | Specified character string (mnemonic). Can be selected from { } (Example: CH2 input coupling -> CHANnel1:COUpling{AC DC GND}) |
| <Boolean> | Indicates ON/OFF. Set to ON, OFF or value (Example: CH2 display ON -> CHANel2:DISPLAY ON) |
| <Character string data> | Arbitrary character string (Example: Comment on screen-data output -> HCOPY:COMMENT "ABCDEF") |
| <Filename> | Gives the name of a file. (Example: Name of file to be saved -> FILE:SAVE:WAVeform: NAME "CASE1") |
| <Block data> | Arbitrary 8-bit data (Example: Response to acquired waveform data -> #800000010ABCDEFHGIJ) |

<Decimal>

<Decimal> indicates a value expressed as a decimal number, as shown in the table below. Decimal values are given in the NR form specified in ANSI X3. 42-1975.

| Symbol | Description | Example |
|--------|---|----------------------|
| <NR1> | Integer | 125 -1 +1000 |
| <NR2> | Fixed point number | 125.0 -.90 +001. |
| <NR3> | Floating point number | 125.0E+0 -9E-1 +.1E4 |
| <NRf> | Any of the forms <NR1> to <NR3> is allowed. | |

- Decimal values which are sent from the controller to this instrument can be sent in any of the forms to <NR3>. In this case, <NRf> appears.
- For response messages which are returned from this instrument to the controller, the form (<NR1> to <NR3> to be used) is determined by the query. The same form is used, irrespective of whether the value is large or small.
- In the case of <NR3>, the "+" after the "E" can be omitted, but the "-" cannot.
- If a value outside the setting range is entered, the value will be normalized so that it is just inside the range.
- If the value has more than the significant number of digits, the value will be rounded.

<Voltage>, <Current>, <Time>, <Frequency>

<Voltage>, <Current>, <Time>, and <Frequency> indicate decimal values which have physical significance. <Multiplier> or <Unit> can be attached to <NRf>. They can be entered in any of the following forms.

| Form | Example |
|-------------------------|---------|
| <NRf><Multiplier><Unit> | 5MV |
| <NRf><Unit> | 5E-3V |
| <NRf><Multiplier> | 5M |
| <NRf> | 5E-3 |

• <Multiplier>

Multipliers which can be used are shown below.

| Symbol | Word | Description |
|--------|-------|-------------|
| EX | Exa | 10^{18} |
| PE | Peta | 10^{15} |
| T | Tera | 10^{12} |
| G | Giga | 10^9 |
| MA | Mega | 10^6 |
| K | Kilo | 10^3 |
| M | Milli | 10^{-3} |
| U | Micro | 10^{-6} |
| N | Nano | 10^{-9} |
| P | Pico | 10^{-12} |
| F | Femto | 10^{-15} |
| A | Atto | 10^{-18} |

• <Unit>

Units which can be used are shown below.

| Symbol | Word | Description |
|--------|-----------|-------------|
| V | Volt | Voltage |
| A | Ampere | Current |
| S | Second | Time |
| HZ | Hertz | Frequency |
| MHZ | Megahertz | Frequency |

- <Multiplier> and <Unit> are not case sensitive.
- "U" is used to indicate " μ ."
- "MA" is used for Mega (M) to distinguish it from milli, except for in the case of Megahertz, which is expressed as "MHZ." Hence, it is not permissible to use "M" (milli) for Hertz.
- If both <Multiplier> and <Unit> are omitted, the default unit will be used.
- Response messages are always expressed in <NR3> form. Neither <Multiplier> nor <Unit> is used, therefore the default unit is used.

<Register>

<Register> indicates an integer, and can be expressed in hexadecimal, octal, or binary as well as a decimal number. <Register> is used when each bit of a value has a particular meaning. <Register> is expressed in one of the following forms.

| Form | Example |
|--|----------|
| <NRf> | 1 |
| #H | #H0F |
| <Hexadecimal value made up of the digits 0 to 9, and A to F> | |
| #Q<Octal value made up of the digits 0 to 7> | #Q777 |
| #B<Binary value made up of the digits 0 and 1> | #B001100 |

- <Register> is not case sensitive.
- Response messages are always expressed as <NR1>.

<Character data>

<Character data> is a specified string of character data (a mnemonic). It is mainly used to indicate options, and is chosen from the character strings given in { }. For interpretation rules, refer to "Header Interpretation Rules" on page 5-4.

| Form | Example |
|------------------------|---------|
| {AC DC DC50 GND} | AC |

- As with a header, the "COMMUnicatE:VERBoSe" command can be used to return a response message in its full form. Alternatively, the abbreviated form can be used.
- The "COMMUnicatE:HEAdEr" command does not affect <character data>.

<Boolean>

<Boolean> is data which indicates ON or OFF, and is expressed in one of the following forms.

| Form | Example |
|--------------------|------------|
| {ON OFF <NRf>} | ON OFF 1 0 |

- When <Boolean> is expressed in <NRf> form, OFF is selected if the rounded integer value is "0" and ON is selected if the rounded integer is "Not 0."
- A response message is always "1" if the value is ON and "0" if it is OFF.

<Character string data>

<Character string data> is not a specified character string like <Character data>. It is an arbitrary character string. A character string must be enclosed in single quotation marks (') or double quotation marks ("").

| Form | Example |
|-------------------------|------------------------|
| <Character string data> | 'ABC' "IEEE488.2-1992" |

- Response messages are always enclosed in double quotation marks.
- If a character string contains a double quotation mark (""), the double quotation mark will be replaced by two concatenated double quotation marks (""). This rule also applies to a single quotation mark within a character string.
- <Character string data> is an arbitrary character string, therefore this instrument assumes that the remaining program message units are part of the character string if no single (') or double quotation mark ("") is encountered. As a result, no error will be detected if a quotation mark is omitted.

<Filename>

Gives the name of a file. The format is as follows.

| Form | Example |
|---|---------------|
| {<NRf> <Character data> <Character string>} | 1 CASE "CASE" |

- If you input an <NRf> value, the system converts the value (after rounding to the nearest integer) to the corresponding 8-character ASCII string. (If you set the value to 1, the name becomes "00000001".) Note that negative values are not allowed.
- If you enter a <character data> argument that is longer than eight characters, only the first twelve characters are used.
- If you enter a <character data> or <character string> argument that is longer than eight characters, only the first sixteen characters are used.
- Response messages always return filenames as <character string> arguments.

<Block data>

<Block data> is arbitrary 8-bit data. <Block data> is only used for response messages. Response messages are expressed in the following form.

| Form | Example |
|---|----------------------|
| #N <N-digit decimal value><Data byte string> | #800000010ABCDEFGHIJ |

- #N
Indicates that the data is <Block data>. "N" is an ASCII character string number (digits) which indicates the number of data bytes that follow.
- <N-digits decimal value>
Indicates the number of bytes of data. (Example: 00000010=10 bytes)
- <Data byte string>
The actual data. (Example: ABCDEFGHIJ)
- Data is comprised of 8-bit values (0 to 255). This means that the ASCII code "0AH," which stands for "NL," can also be a code used for data. Hence, care must be taken when programming the controller.

5.5 Synchronization with the Controller

Overlap Commands and Sequential Commands

There are two kinds of command; overlap commands and sequential commands. Execution of an overlap command may start before execution of the previously sent command is completed.

The "CHANnel1:VDIV" command, for example, is a sequential command. Assume that you set a new V/div value and immediately request return of the new value, as follows:

```
:CHANnel1:VDIV 5V;VIDV?<PMT>
```

In this case, the oscilloscope always returns the newest setting ("5V"). This is because it always completes processing of the current sequential command (in this case, "VDIV 5V") before moving on to the next command ("VIDV?").

In contrast, assume that you begin a file load and then immediately query the V/div value:

```
:FILE:LOAD:SETup:EXECute "CASE1";:  
CHANnel1:VDIV?
```

Because "FILE:LOAD:SETup:EXECute "CASE1"" is an overlapped command, the oscilloscope will advance to the "CHANnel1:VDIV?" command before it finishes the load. The returned V/div value will not show the newest setting, but will rather show the setting in use before the setup was changed.

Obviously, use of overlapped commands may in some cases produce inappropriate results. Where necessary, you can avoid such problems as described below.

Synchronization with an Overlap Command

Using the *WAI Command

The *WAI command causes the commands which follow it to wait until an overlap command has been executed.

```
Example:COMMunicate:OPSE #0040;:FILE:  
LOAD:SETup:EXECute "CASE1";*WAI;:  
CHANnel1:VDIV?<PMT>
```

The "COMMunicate:OPSE" command is used to designate which commands are to be subject to the *WAI command. In the above example, only auto set-up is designated.

Since a *WAI command is executed just before "CHANnel1:VDIV?," "CHANnel1:VDIV?" will not be executed until auto set-up has been completed.

5.5 Synchronization with the Controller

Using the COMMUnicatE:OVERlap Command

The "COMMUnicatE:OVERlap" command is used to enable or disable overlap operation.

Example :COMMUnicatE:OVERlap #HFFBF;:FILE:
LOAD:SETup:EXECute "CASE1";:
CHANnel1:VDIV:VALue?<PMT>

The "COMMUnicatE:OVERlap #HFFBF" command disables overlapped operation of the medium access command, while enabling all other overlap-type operations. The oscilloscope will therefore handle "FILE:LOAD:SETup:EXECute "CASE1"" as sequential command, ensuring that the "CHANnel1:VIDV?" command (in the above example) will not execute until file loading is completed.

Using the *OPC Command

The *OPC command causes the OPC bit (bit 0) of the standard event register (page 7-3) to be set to "1" when an overlap operation has been completed.

Example :COMMUnicatE:OPSE #H0040;*ESE 1;
*ESR?;*SRE 32;:FILE:LOAD:SETup:
EXECute "CASE1";*OPC<PMT>
(Response to *ESR? is decoded.)
(Service request is awaited.)
CHANnel1:VDIV?<PMT>

The "COMMUnicatE:OPSE" command is used to designate which commands are to be subject to the *OPC command. In the above example, only medium access commands are designated.

*ESE 1 and *SRE 32 stipulate that a service request is generated only when the OPC bit is set to "1." *ESR? is used to clear the standard event register. In the above example, "CHANnel1:VIDV?" will not be executed until a service request is generated.

Using the *OPC? Query

The *OPC? query generates a response when an overlap operation has been completed.

Example :COMMUnicatE:OPSE #H0040;:FILE:
LOAD:SETup:EXECute "CASE1";
*OPC?<PMT>
(Response to *OPC? is decoded.)
:CHANnel1:VDIV?<PMT>

The "COMMUnicatE:OPSE" command is used to designate which commands are to be subject to the *OPC? command. In the above example, only medium access commands are designated.

Since *OPC? does not generate a response until an overlap operation is completed, file loading will have been completed when a response to *OPC? is read.

Note

Most commands are sequential commands. Commands used in Chapter 6 are sequential commands unless otherwise specified.

Synchronization with Non-Overlap Commands

Synchronization is sometimes required for reasons other than communications-related reasons, such as the activation of a trigger, even if a sequential command is used.

For example, if a "next program" message is transmitted to make an inquiry about the waveform data which has been acquired using single mode as the trigger mode, the "WAVeform:SEND?" command is sometimes executed whether acquisition has been completed or not, causing a command execution error.
:TRIGger:MODE SINGLE;:START;:WAVeform:
SEND?<PMT>

In this case, synchronization with the time at which acquisition is completed must be accomplished, as shown next.

Using STATus:CONDition? Query

A "STATus:CONDition?" query is used to make a query about the contents of the condition register (page 7-4). It is possible to judge whether acquisition is in progress or not by reading bit 0 of the condition register. Bit 0 is "1" if acquisition is in progress, and "0" if acquisition is stopped.

Example :TRIGger:MODE SINGLE;:START<PMT>
:STATus:CONDition?<PMT>
(Returns to the previous status if bit 0 is found to be "1" when the response is decoded.)
:WAVeform:SEND?<PMT>

A "WAVeform:SEND?" query will not be executed until bit 0 of the condition register has been set to "0."

Using the Extended Event Register

Changes in the condition register are reflected in the extended event register (page 7-4).

Example :STATus:FILTter1 FALL;:STATus:

```
EESE 1;EESR?;*SRE 8;:TRIGger:  
MODE SINGLE;:START<PMT>  
(Response to "STATus:EESR?" is decoded.)  
(Service request is awaited.)  
:WAVeform:SEND?<PMT>
```

The "STATus:FILTter1 FALL" command sets the transition filter such that Bit 0 (FILTter1) of the Extended Event Register sets to 1 when Bit 0 of the Condition Register changes from 1 to 0.

"STATus:EESE 1" is a command used only to reflect the status of bit 0 of the extended event register in the status byte.

"STATus:EESR?" is used to clear the extended event register.

The *SRE command is used to generate a service request caused solely by the extended event register.

"WAVeform:SEND?" will not be executed until a service request is generated.

Using the COMMUnicatE:WAIT Command

The "COMMUnicatE:WAIT" command halts communications until a specific event is generated.

Example :STATus:FILTter1 FALL;:STATus:

```
EESR?;:TRIGger:MODE SINGLE;  
START<PMT>  
(Response to "STATus:EESR?" is decoded.)  
:COMMUnicatE:WAIT 1;:WAVeform:  
SEND?<PMT>
```

For a description of "STATus:FILTter1 FALL" and "STATus:EESR?", refer to "Using the extended event register" on this page.

"COMMUnicatE:WAIT 1" means that communications is halted until bit 0 of the extended event register is set to "1."

6.39 Common Command Group

6.39 Common Command Group

The commands in the common group are defined in the IEEE 488.2-1987 and are independent of the instrument's functions. There are no front panel keys that correspond to the commands in this group.

*CAL? (CALibrate)

Function Performs calibration and queries the result.
Syntax *CAL?
Example *CAL? -> 0
Description If the calibration terminates normally, "0" is returned. If an error is detected, "1" is returned.

*CLS (CLear Status)

Function Clears the standard event register, extended event register, and error queue.
Syntax *CLS
Example *CLS
Description • If the *CLS command is located immediately after the program message terminator, the output queue is also cleared.
• For details on the register and queue, see chapter 7.

*ESE (standard Event Status Enable register)

Function Sets the standard event enable register or queries the current setting.
Syntax *ESE {<NRf>}
*ESE?
<NRf>=0 to 255
Example *ESE 251
*ESE? -> 251
Description • Specify the value as a sum of decimal values of each bit.
• For example, specifying "*ESE 251" will cause the standard enable register to be set to "11111011." In this case, bit 2 of the standard event register is disabled which means that bit 5 (ESB) of the status byte register is not set to "1," even if a "query error" occurs.
• The default value is "*ESE 0" (all bits disabled).
• A query using *ESE? will not clear the contents of the standard event enable register.
• For details on the standard event enable register, see page 7-3.

*ESR? (standard Event Status Register)

Function Queries the standard event register and clears the register.

Syntax *ESR?

Example *ESR? -> 32

Description

- A sum of decimal values of each bit is returned.
- You can check what type of events occurred when an SRQ is generated.
- For example, if a value of "32" is returned, this indicates that the standard event register is set to "00100000." In this case, you can see that the SRQ occurred due to a "command syntax error."
- A query using *ESR? will clear the contents of the standard event register.
- For details on the standard event register, see page 7-3.

*IDN? (IDEntify)

Function Queries the instrument model.

Syntax *IDN?

Example *IDN? -> YOKOGAWA,701210,0,F1.10

Description The information is returned in the following form: <Manufacturer>,<Model>,<Serial No.>,<Firmware version>
In actuality, <Serial No.> is not returned (always 0).

*LRN? (LeaRN)

Function Queries collectively the current settings of the following command groups.

*OPC (OPeration Complete)

| | |
|--------------------|--|
| Function | Sets a “1” to bit 0 (OPC bit) of the standard event register bit upon the completion of the specified overlap command. |
| Syntax | *OPC |
| Example | *OPC |
| Description | <ul style="list-style-type: none"> For the description regarding how to synchronize the program using *OPC, see page 5-7. The COMMUnicate:OPSE command is used to specify the overlap command. If *OPC is not the last command of the message, the operation is not guaranteed. |

*OPC? (OPeration Complete)

| | |
|-------------|--|
| Function | If *OPC? is transmitted and the specified overlap command is completed, ASCII code "1" is returned. |
| Syntax | *OPC? |
| Example | *OPC? -> 1 |
| Description | <ul style="list-style-type: none"> For the description regarding how to synchronize the program using *OPC?, see page 5-7. The COMMUnicate:OPSE command is used to specify the overlap command. If *OPC? is not the last command of the message, the operation is not guaranteed. |

***OPT? (OPTION)**

| | |
|-------------|---|
| Function | Queries the installed options. |
| Syntax | *OPT? |
| Example | *OPT? -> CH25MW,PCCARD,HD,ETHER, USERDEFINE,PROBEPOWER |
| Description | <ul style="list-style-type: none"> • Returns the presence of <Channel>, <HD>, <User-defined equation>, and <32-bit extended logic input> • The *OPT? query must be the last query of the program message. An error occurs if there is a query after this query. |

***PSC (Power-on Status Clear)**

| | |
|----------|--|
| Function | Sets whether or not to clear the registers below at power on or queries the current setting. The register is cleared when the value rounded to an integer is a non-zero value. <ul style="list-style-type: none"> • Standard event enable register • Extended event enable register • Transition filter |
| Syntax | *PSC {<NRF>} |
| | *PSC? <NRF>=0(not clear), non-zero (clear) |
| Example | *PSC 1 *PSC? -> 1 |

Description For details on the registers, see chapter 7.

***RST (ReSeT)**

| | |
|----------|--|
| Function | Collectively initializes the current settings of the following command groups. ACCumulate, ACQuire, CHANnel<x>, TIMEbase, TRIGger |
| Syntax | *RST |
| Example | *RST |

Description Also clears *OPC and *OPC? commands that have been sent earlier.

***SRE (Service Request Enable register)**

| | |
|-------------|--|
| Function | Sets the service request enable register or queries the current setting. |
| Syntax | *SRE <NRF> *SRE? <NRF>=0 to 255 |
| Example | *SRE 239 *SRE? -> 175 |
| Description | <ul style="list-style-type: none"> • Specify the value as a sum of decimal values of each bit. • For example, specifying “*SRE 239” will cause the service request enable register to be set to “11101111.” In this case, bit 4 of the service request enable register is disabled which means that bit 4 (MAV) of the status byte register is not set to “1,” even if “the output queue is not empty.” • Bit 6 (MSS) of the status byte register is the MSS bit itself, and therefore, is ignored. • The default value is “*SRE 0” (all bits disabled). • A query using *SRE? will not clear the contents of the service request enable register. • For details on the service request enable register, see page 7-1. |

***STB? (SStatus Byte)**

| | |
|-------------|--|
| Function | Queries the status byte register. |
| Syntax | *STB? |
| Example | *STB? -> 4 |
| Description | <ul style="list-style-type: none"> • The sum of the bits is returned as a decimal value. • Since the register is read without executing serial polling, bit 6 is a MSS bit not RQS. • For example, if a value of “4” is returned, this indicates that the status byte register is set to “00000100.” In this case, you can see that “the error queue is not empty” (an error occurred). • A query using *STB? will not clear the contents of the status byte register. • For details on the status byte register, see page 7-2. |

***TST?**

| | |
|----------|--|
| Function | Performs a self-test and queries the result. The self test involves internal memory tests. |
| Syntax | *TST? |

Registers and Queues which Affect the Status Byte

Registers which affect each bit of the status byte are shown below.

- Standard event register : Sets bit 5 (ESB) of status byte to "1" or "0.."
- Output queue : Sets bit 4 (MAV) of status byte to "1" or "0.."
- Extended event register : Sets bit 3 (EES) of status byte to "1" or "0.."
- Error queue : Sets bit 2 (EAV) of status byte to "1" or "0.."

Enable Registers

Registers which mask a bit so that the bit does not affect the status byte, even if the bit is set to "1," are shown below.

- Status byte : Masks bits using the service request enable register.
- Standard event register : Masks bits using the standard event enable register.
- Extended event register : Masks bits using the extended event enable register.

Writing/Reading from Registers

The *ESE command is used to set bits in the standard event enable register to "1" or "0..," and the *ESE query is used to check whether bits in that register are set to "1" or "0..". For details of these commands, refer to Chapter 6.

7.2 Status Byte

Overview of Status Byte

Bits 0, 1 and 7

Not used (always "0")

Bit 2 EAV (Error Available)

Set to "1" when the error queue is not empty, i.e. when an error occurs. For details, refer to page 7-5.

Bit 3 EES (Extended Event Summary Bit)

Sets to "1" when the logical "AND" of an Extended Event Register bit and the corresponding Enable Register bit is equal to "1."—that is, when an event takes place in the instrument. Refer to page 7-4.

Bit 4 MAV (Message Available)

Set to "1" when the output queue is not empty, i.e. when there is data which is to be output when an query is made. Refer to page 7-5.

Bit 5 ESB (Event Summary Bit)

Set to "1" when the logical AND of the standard event register and the corresponding enable register is "1," i.e. when an event takes place in the instrument. Refer to page 7-3.

Bit 6 RQS (Request Status)/MSS (Master Summary Status)

Sets to "1" when the logical "AND" of any one of the Status Byte bits (other than bit 6) and the corresponding Service Request Enable Register bit becomes "1"—that is, when the instrument is requesting service from the controller. RQS is set to "1" when MSS changes from "0" to "1," and is cleared when a serial poll is performed or when MSS changes to "0..".

Bit Masking

To mask a bit in the status byte so that it does not cause an SRQ, set the corresponding bit of the service request enable register to "0..".

For example, to mask bit 2 (EAV) so that no service will be requested, even if an error occurs, set bit 2 of the service request enable register to "0..". This can be done using the *SRE command. To query whether each bit of the service request enable register is "1" or "0..," use *SRE?. For details of the *SRE command, refer to Chapter 6.

Operation of the Status Byte

A service request is issued when bit 6 of the status byte becomes "1." Bit 6 becomes "1" when any of the other bits becomes "1" (or when the corresponding bit in the service request enable register becomes "1").

For example, if an event takes place and the logical OR of each bit of the standard event register and the corresponding bit in the enable register is "1," bit 5 (ESB) will be set to "1." In this case, if bit 5 of the service request enable register is "1," bit 6 (MSS) will be set to "1," thus requesting service from the controller.

It is also possible to check what type of event has occurred by reading the contents of the status byte.

Reading from the Status Byte

The following two methods are provided for reading the status byte.

- **Inquiry Using the *STB? Query**

Making an query using the *STB? query sets bit 6 to MSS. This causes the MSS to be read. After completion of the read-out, none of the bits in the status byte will be cleared.

- **Serial Poll**

Execution of a serial poll changes bit 6 to RQS. This causes RQS to be read. After completion of the read-out, only RQS is cleared. Using a serial poll, it is not possible to read MSS.

Clearing the Status Byte

No method is provided for forcibly clearing all the bits in the status byte. Bits which are cleared are shown below.

- **When an Query is Made Using the *STB? Query**

No bit is cleared.

- **When a Serial Poll is Performed**

Only the RQS bit is cleared.

- **When the *CLS Command is Received**

When the *CLS command is received, the status byte itself is not cleared, but the contents of the standard event register (which affects the bits in the status byte) are cleared. As a result, the corresponding bits in the status byte are cleared, except bit 4 (MAV), since the output queue cannot be emptied by the *CLS command. However, the output queue will also be cleared if the *CLS command is received just after a program message terminator.

7.3 Standard Event Register

Overview of the Standard Event Register

| | | | | | | | |
|-----|-----|-----|-----|-----|-----|-----|-----|
| 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| PON | URQ | CME | EXE | DDE | QYE | RQC | OPC |

Bit 7 PON (Power ON)

Bit 7 PON (Power ON) Set to "1" when power is turned ON

Bit 6 URQ (User Request)

Not used (always "0")

Bit 5 CME (Command Error)

Set to "1" when the command syntax is incorrect.

Examples: Incorrectly spelled command name; "9" used in octal data.

Bit 4 EXE (Execution Error)

Set to "1" when the command syntax is correct but the command cannot be executed in the current state.

Examples: Parameters are outside the setting range: an attempt is made to make a hard copy during acquisition.

Bit 3 DDE (Device Dependent Error)

Set to "1" when execution of the command is not possible due to an internal problem in the instrument that is not a command error or an execution error.

Example: The circuit breaker is reset.

Bit 2 QYE (Query Error)

Set to "1" if the output queue is empty or if the data is missing even after a query has been sent.

Examples: No response data; data is lost due to an overflow in the output queue.

Bit 1 RQC (Request Control)

Not used (always "0")

Bit 0 OPC (Operation Complete)

Set to "1" when the operation designated by the *OPC command has been completed. Refer to Chapter 6.

Bit Masking

To mask a bit in the standard event register so that it does not cause bit 5 (ESB) of the status byte to change, set the corresponding bit in the standard event enable register to "0."

For example, to mask bit 2 (QYE) so that ESB will not be set to "1," even if a query error occurs, set bit 2 of the standard event enable register to "0." This can be done using the *ESE command. To inquire whether each bit of the standard event enable register is "1" or "0," use the *ESE?. For details of the *ESE command, refer to Chapter 6.

7.3 Standard Event Register/7.4 Extended Event Register

Operation of the Standard Event Register

The standard event register is provided for eight different kinds of event which can occur inside the instrument. Bit 5 (ESB) of the status byte is set to "1" when any of the bits in this register becomes "1" (or when the corresponding bit of the standard event enable register becomes "1").

Examples

1. A query error occurs.
2. Bit 2 (QYE) is set to "1."
3. Bit 5 (ESB) of the status byte is set to "1" if bit 2 of the standard event enable register is "1."

It is also possible to check what type of event has occurred inside the instrument by reading the contents of the standard event register.

Reading from the Standard Event Register

The contents of the standard event register can be read by the *ESR command. After completion of the read-out, the register will be cleared.

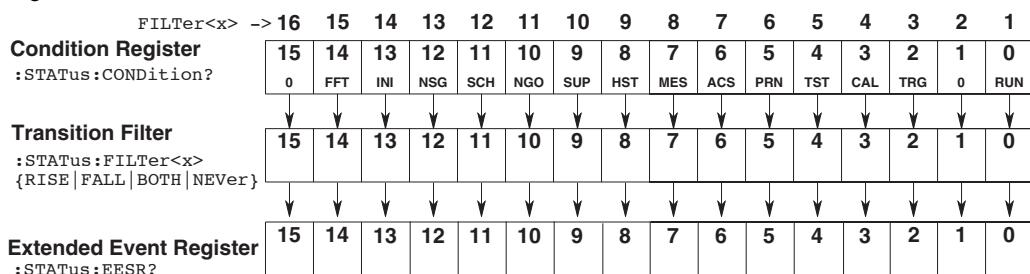

Clearing the Standard Event Register

The standard event register is cleared in the following three cases.

- When the contents of the standard event register are read using *ESR?
- When the *CLS command is received
- When power is turned ON again

7.4 Extended Event Register

Reading the extended event register tells you whether changes in the condition register (reflecting internal conditions) have occurred. A filter can be applied which allows you to decide which events are reported to the extended event register.

The meaning of each bit of the condition register is as follows.

| | |
|------------------------------|---|
| Bit 0 RUN (Running) | Set to "1" during acquisition. |
| Bit 2 TRG (Awaiting Trigger) | Set to "1" when waiting for a trigger. |
| Bit 3 CAL (Calibrating) | Set to "1" during calibration. |
| Bit 4 TST (Testing) | Set to "1" during self-test. |
| Bit 5 PRN (Printing) | Set to "1" while the internal printer is in operation, data is being output to the external printer (USB or network printer), or screen image data is being stored. |
| Bit 6 ACS (Accessing) | Set to "1" while the floppy disk, Zip disk, PC card, internal hard disk, or external disk drive (SCSI or network devices) is being accessed. |
| Bit 7 MES (Measuring) | Set to "1" when automated measurement of waveform parameters or cursor measurement is in progress. |
| Bit 8 HST (History Search) | Set to "1" while executing history search. |
| Bit 9 SUP (Set-up) | Set to "1" during auto set-up. |
| Bit 10 NGO (Go/No-Go) | Set to "1" while performing GO/NO-GO determination. |
| Bit 11 SCH (Search) | Set to "1" while executing edge/pattern search. |
| Bit 12 NSG (N-Single) | Set to "1" during continuous acquisition when the trigger mode is set to single (N). |
| Bit 13 INI (Initializing) | Sets to "1" during initialization. |
| Bit 14 FFT | Set to "1" while performing the FFT. |

The filter is applied to each bit of the condition register separately, and can be selected from the following.

Note that the numbering of the bits used in the filter setting differs from the actual bit number (1 to 16 vs. 0 to 15).

| | |
|-------|--|
| Rise | The bit of the extended event register becomes "1" when the bit of the condition register changes from "0" to "1." |
| Fall | The bit of the extended event register becomes "1" when the bit of the condition register changes from "1" to "0." |
| Both | The bit of the extended event register becomes "1" when the bit of the condition register changes from "0" to "1," or from "1" to "0." |
| Never | The bit of the extended event register is disabled and always "0." |

7.5 Output Queue and Error Queue

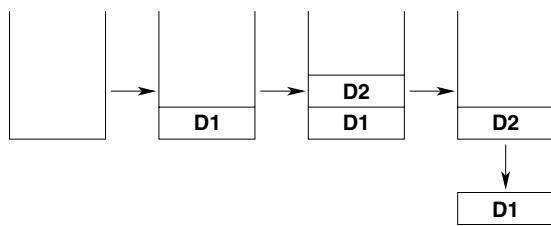

Overview of the Output Queue

The output queue is provided to store response messages to queries. For example, when the :WAVEFORM:SEND? query is sent to request output of the acquired waveform, the response data will be stored in the output queue until it is read out.

The example below shows that data is stored record by record in the output queue, and is read out oldest item first, newest item last. The output queue is emptied in the following cases (in addition to when read-out is performed).

- When a new message is received from the controller
- When dead lock occurs (page 5-2)
- When a device clear command (DCL or SDC) is received
- When power is turned ON again

The output queue cannot be emptied using the *CLS command. To see whether the output queue is empty or not, check bit 4 (MAV) of the status byte.

Overview of the Error Queue

The error queue stores the error No. and message when an error occurs. For example, if the controller sends an incorrect program message, the number, “113, “Undefined header”,” and the error message are stored in the error queue, when the error is displayed. The contents of the error queue can be read using the :STATus:ERROr? query. As with the output queue, messages are read oldest first, newest last (refer to the previous page).

If the error queue becomes full, the final message will be replaced by message “350, “Queue overflow”.”

The error queue is emptied in the following cases (in addition to when read-out is performed).

- When the *CLS command is received
- When power is turned ON again

To see whether the error queue is empty or not, check bit 2 (EAV) of the status byte.

Appendix 3 Overview of IEEE 488.2-1992

The GP-IB interface provided with DL750P conforms to IEEE 488.2-1992. This standard requires the following 23 points be stated in this document. This Appendix describes these points.

1 Subsets Supported by IEEE 488.1 Interface Functions

Refer to Section 1.4 "GP-IB Interface Specifications".

2 Operation of Device when the Device is Assigned to an Address Other than Addresses 0 to 30.

The DL750/DL750P does not allow assignment to an address other than 0 to 30.

3 Reaction when the User Changes the Address

The current address is changed when a new address is set using MISC. The newly set address is valid until another new address is set.

4 Device Set-up at Power ON.Commands which can be Used at Power ON

Basically, the previous settings (i.e. the settings which were valid when power was turned OFF) are valid. All commands are available at power ON.

5 Message Transmission Options

a Input Buffer Size

4096 bytes

b Queries which Return Multiple Response Messages

Refer to Chapter 6, "Command List".

c Queries which Generate Response Data during Analysis of the Syntax

Every query generates a response data when analysis of the syntax is completed.

d Queries which Generate Response Data during Reception

No query generates response data when the query is received by the controller.

e Commands Consisting of Parameters which Restrict One Other

Some commands, like the :CHANnel<x>:VOLTage:PROBe and VDIV, have parameters which restrict unilaterally, but no commands have parameters which restrict bilaterally.

6 Options Included in Command Function Elements and Composite Header Elements

Refer to Chapters 5 and 6.

7 Buffer Size which Affects Transmission of Block Data

During transmission of block data, the output queue is extended according to the size of the data blocks.

8 List of Program Data Elements which can be Used in Equations, and Nesting Limit

No equations can be used.

9 Syntax of Response to Queries

Refer to the description of the commands given in Chapter 6.

10 Communications between Devices which do not Follow the Response Syntax

Not supported.

11 Size of Data Block of Response Data

1 to 2004000 bytes

12 List of Supported Common Commands

Refer to Section 6.38 "Common Command Group".

13 Condition of Device when Calibration is Successfully Completed

Same as the one under which measurements are performed

14 Maximum Length of Block Data which can be Used for Definition of *DDT

Trigger Macro

Not supported

15 Maximum Length of Macro Label Used in Definition of Macro, Maximum Length of Block Data which can be Used for Definition of Macro, Processing when Recursion is Used in Definition of Macro
Macro functions are not supported.

16 Response to *IDN?

Refer to Section 6.39 "Common Command Group".

17 Size of Storage Area for Protected User Data for PUD and *PUD?

*PUD and *PUD? are not supported.

18 Length of *RDT and *RDT? Resource Name

*RDT and *RDT? are not supported.

19 Change in Status Due to *RST, *LRN?, *RCL and *SAV

***RST, *LRN?**

Refer to Section 6.39 "Common Command Group".

***RCL, *SAV**

These commands are not supported.

20 Execution Range of Self-Test Using the *TST?

All the memory tests (for each internal memory) given in the Self Test menu displayed using MISC can be executed.

21 Structure of Extended Return Status

Refer to Chapter 7.

22 To Find out whether Each Command is Performed in Parallel or Sequentially

Refer to Section 5.5 "Synchronization with the Controller" and to Chapter 6.

23 Description of Execution of Each Command

Refer to Chapter 6 of this manual and to the User's Manuals IM 701210-05E and IM 701210-06E.
