## SECTION I - INTRODUCTION

The Keithley Model 502 is a battery operated, portable milliohmmeter for measuring resistances from 0.00003 to 1000 ohms. The instrument employs an AC testing method, eliminating zero drift and permitting resistance readings in the presence of DC currents. The reading is presented on a linear scale panel meter.

Typical applications of the instrument include measurement of contact resistance, conductivity of semi-conductor samples, fuse and squib testing, and electrolyte conductivity.

Maximum power dissipation in the sample is 2 microwatts, permitting the measurement of detonator fuses without danger of detonation. In the measurement of contact resistance, the model 502 may be considered a "dry circuit" tester. However, the instrument may be used in the presence of DC biasing currents to measure the change in resistance caused by these currents.

FIGURE 1. Keithley Model 502 Milliohmmeter with carrying case open.

RANGES: The test current, the input voltage drop, and the power dissipation $\left(P_{d}=2 I_{a v} E_{a v}\right)$ for full-scale readings on each range are given below:

| Range, Ohms | Average Applied Current, Milliamperes | Average Voltage Drop, Microvolts | Maximum Dissipation in Sample, Microwatts |
| :---: | :---: | :---: | :---: |
| 0.001 | 10 | 10 | 0.2 |
| 0.003 | 10 | 30 | 0.6 |
| 0.01 | 10.00 | 100 | 2.00 |
| 0.03 | 3.33 | 100 | 0.66 |
| 0.1 | 1.00 | 100 | 0.2 |
| 0.3 | 0.33 | 100 | 0.066 |
| 1 | 0.1 | 100 | 0.02 |
| 3 | 0.2 | 600 | 0.24 |
| 10 | 0.06 | 600 | 0.072 |
| 30 | 0.02 | 600 | 0.024 |
| 100 | 0.006 | 600 | 0.0072 |
| 300 | 0.002 | 600 | 0.0024 |
| 1000 | 0.0006 | 600 | 0.00072 |

ACCURACY: $3 \%$ of full scale on all ranges except the 0.001 -ohm range, where it is $5 \%$ of full scale. Less than $2 \%$ error is added in measuring samples with a series reactance of $4 \%$ of sample resistance.

OUTPUT: Meter only.
SAFETY AND RELIABILITY: Maximum power dissipation in the sample with improper range setting is three milliwatts. Maximum dissipation caused by instrument component failure and improper range setting is six milliwatts.

INPUT ZERO: Lever switch prevents off-scale meter indications while changing samples.

SPEED OF RESPONSE: Five seconds to $90 \%$ of final reading on all ranges.
ZERO DRIFT: None.
REPEATABILITY: Within $2 \%$.
WARMUP TIME: Within 30 seconds.

BATTERY LIFE: 360 hours minimum.
BATTERY TEST: An internal resistance standard is measured in the Battery Test Position to provide a complete check of battery condition and proper instrument operation.

BATTERY COMPLEMENT: Two RM 401R, two RM 42R, one 412, one 413.
TUBE COMPLEMENT: One 6418, four 6419.
TRANSISTOR COMPLEMENT: Four 2N1381.
ACCESSORIES FURNISHED: Mode1 5021 Current and Voltage Leads; one set of alligator clips; one set Klipson adapters; mating connectors.

CONNECTORS: Amphenol 80 C and $80-\mathrm{PC} 2 \mathrm{~F}$ receptacles.
DIMENSIONS: 9 inches high $x 6$ inches wide $x 7$ inches deep.
NET WEIGHT: 7-1/2 pounds.

    SECTION III - OPERATION
```

## .A. CONNECTIONS

(1) Lower resistances (less than 3 ohms).

Each test lead has two clips, one with a red insulator and the other with a black insulator. Use both test leads to make a connection, making sure like-color clips are on the same side of the sample (see Figure 2). Connect the current supply leads to the sample at any point which assures current flow through the entire sample. This connection may include the leads on the sample.

FIGURE 2.

Connect the voltmeter leads across only that part of the sample which is to be measured, as shown in Figure 2. If the terminal or test leads of the resistance being measured are included within the voltmeter clips, the reading will include the resistance of these leads.

NOTE
Do not connect the red clips to the black clips. The clip-to-sample resistance of both voltmeter clips are added in series with the unknow, and large errors can result.
(2) Higher resistances (3 ohms and greater).

For ranges over 3 ohms full scale, the clip contact resistance is insignificant compared with the full scale value, so voltage and current leads may be paired and the standard two-terminal ohmmeter method employed. Of course, the four-terminal method above may be used, but the two terminal method is faster for repeated testing.

## B. PROCEDURE

Turn the power ON while the READ-SHORT Switch is at SHORT. The instrument will stabilize in about 15 seconds.

Connect the leads to the sample as outlined above. Then move the READSHORT switch to READ. Rotate the OHMS FULL SCALE switch until a suitable on-scale reading is obtained.

The READ-SHORT switch shorts the voltage input in the SHORT position. It keeps the meter pointer on scale while the test leads are being connected to an unknown. If an overload is applied to the input by inadvertently opening the READ-SHORT switch, no damage will result. However, approximately 30 seconds will be required for the amplifier to recover.

## C. BATTERY TEST

Before a reading is made, it may be desirable to check overall circuit operation. This is done by rotating the range switch to BATT. TEST and switching the READ-SHORT switch to READ. The meter should read within $\frac{1}{2}$ divisions of the red line on the meter face marked BATTERY TEST. Failure of the unit to read within these limits indicates a circuit failure which, in most cases, will be battery failure. Consult SECTION V - MAINIENANCE for battery changes or troubleshooting information.

## D. PRECAUTIONS

On full scale ranges of one ohm and below, the amplifier has sensitivities in the microvolt region and a pass band which includes 60 cps. Thus, a loop in the voltage leads which encloses any 60 cps magnetic field may give a meter indication. Care should be exercised to avoid such magnetic loops. Care should also be taken in shielding critical circuits to avoid 60 cps pickup from electric fields; in general, however, the electrostatic pickup is not serious at the impedance involved. One way to test for pickup is to remove the current supply leads with the voltage leads connected to the sample. If no reading appears on the meter, no pickup is present. If some reading does occur due to the presence of 60 cps magnetic field, it may be reduced to a minimum by rotating the meter for minimum pickup. In any case, the instrument reads correctly above any residual reading. For example, if the 502 reads, say, . 002 ohms due to the presence of stray fields with the voltmeter leads shorted, a .003 ohm resistance being tested will still read .003 ohms. This is because the 60 cps signal is superimposed on the 100 cps square wave test signal. Thus the 60 cps signal is not rectified and the meter reads only the rectified square wave.

Because of the AC technique employed, inductive and capacitive components in the test impedance may cause some waveform distortion and erroneous readings. Series inductive impedance (at 100 cps ) less than $20 \%$ of the resistance cause the reading to be less than $2 \%$ high. Shunt capacitive admittance (at 100 cps ) less than $6 \%$ of the conductance cause the reading to be less than $2 \%$ low. Listed below are the limiting values of inductance and capacitance to cause $2 \%$ error at full scale on any range:

| RANGE | MAX SERIES INDUCTANCE | MAX SHUNT CAPACITANCE |
| :---: | :---: | :---: |
| . 001 ohms | . 3 microhenries |  |
| . 003 | . 9 | over |
| . 01 | 3 | 1000 microfarad |
| .03 | 9 |  |
| . 1 | 30 |  |
| . 3 | 90 | 750 microfarad |
| 1.0 | . 3 millihenries | 250 |
| 3.0 | . 9 | 75 |
| 10.0 | 3 | 25 |
| 30 | 9 | 7.5 |
| 100 | 30 | 2.5 |
| 300 | 90 | . 75 |
| 000 | . 3 henries | .25 |

It is well to remember that basically, the Model 502 is measuring the voltage acrosis the sample resistance due to current flow in the sample. So long as the sample current is generated by the Model 502, no difficulties should be encountered. However, if other currents are flowing in the sample in addition to the test current, these currents must be either small compared with the test current or essentially dc. The Model 502 will read a resistor in the milliohm region which is carrying more than 50 amperes of direct current, but even .01 amperes of alternating current whose frequency is within the pass band of the amplifier will cause a serious error.

When measuring samples across which a dc voltage greater than about .05 volts may appear, a blocking capacitor should be used in series with one current lead and another capacitor in series with one voltage lead. Use 1000 mfd at a voltage rating sufficient to handle the dc sample voltage.

The setup is shown in Fig. 3. If this arrangement is to be used on the ranges below. 3 ohm, also include $r$ as shown. This resistor is to provide a d.c. return path for the output transistor, QL.

FIGURE 3

Values of $r$ and $C$ are shown below:

| Range |  | $\mathbf{C}$ | Added error |
| :--- | ---: | :--- | :---: |
|  | 100 | 1000 mfd | $-1 \%$ |
| .1 | 47 | 1000 | $-3 \%$ |
| .03 | 10 | 4000 | $-6 \%$ |
| .01 | 10 | 4000 | $-6 \%$ |
| .003 | 10 | 4000 | $-6 \%$ |

The standard method of measuring resistance assumes that test lead resistance is negligible. When measuring resistances at or below the level of lead resistance, a more sophisticated approach is required.

The four-terminal method of resistance measurement consists of supplying current from an isolated current generator to the sample, and measuring the voltage drop across the sample with an isolated voltmeter. The generator is made to supply constant current regardless of lead resistance so that no errors occur due to current lead connection. The voltmeter has large enough input resistance so that the voltage lead resistance does not cause any error. Since there is no current error and voltage error, the resistance is read correctly.

The 502 circuit consists of two parts: a 100 cps transistor squarewave generator supplies the current across the sample and the AC microvolt meter measures the voltage drop. The panel meter is calibrated directly in ohms on a linear scale. Refer to the circuit diagram, DR 12189-C.
(1) Square Wave Generator. The 100 cps square wave is generated by a transistor multivibrator consisting of Q1 and Q2. R146 is a symmetry control which is set at the factory to give a symmetrical square wave. This adjustment is necessary to insure no change in reading when the current leads are reversed. Q3 and Q4 serve as a power amplifier. Transistor QL acts essentially as a 100 cps switch connecting and disconnecting Bl across the sample and series resistors RI. 32 through Rl42. Due to the fact that the output peak voltage is more than $95 \%$ of the mercury battery voltage, the change in square-wave amplitude with change of transistor parameters is very small. B6 supplies a small negative bias current through R151 to the output transistor to insure good cut off characteristics, at a high ambient temperature.
(2) AC Amplifier. The ac amplifier is a conventional vacuum tube voltmeter with meter current feedback. The input signal is matched to the vacuum tube input by an input transformer on the more sensitive ranges. Above 1 ohm , the input transformer is not used.

The input voltage is compared to the feedback voltage through R101 and RlO2 into the grid of V1. V1, V2, V3, V4, and V5 amplify the error signal. The output voltage is full-wave rectified by D1 and D2 to supply indicating meter current. The ac current through the meter and rectifiers flows in Rl28, Rl29 or R130 to supply feedback voltage to the first stage. The dividers R103 and R126 or R127 allow separate calibration of the ranges which employ transformer input and the ranges which do not.

ON BATTERY TEST, the unit is automatically placed on the 1000 ohm range. A 500 ohm resistor, R149, is connected into the test position and the external current and voltage leads are disconnected. Since battery current drain is essentially the same on all ranges, this test will indicate faulty batteries immediately by giving a reading less than normal.

```
*
SECTION V - MAINTENANCE
```

A. BATTERIES

Under ncrmal conditions the only maintenance required will be the replacement of batteries. To reach the batteries, remove the four screws at the rear and slide the instrument out of the case. The batteries are all located in holders at the top of the instrument.

BI, supplying the current generator, and B3, which supplies the vacuum tube filaments, should have a useful life of about 460 hours unless the instrument is used continuously on the lowest three ranges. This may shorten the life of BI to 360 hours. BL, which supplies plate potential to the output tube should last through about two changes of B1 and B3. B2, the bias battery, B5, the plate supply for the amplifier, and B6, the negative bias for the output transistor, should last about two years. To be certain of always having fresh batteries, a good practice would be to change all batteries whenever one of the set needs replacement.

## B. TROUBLE-SHOOTING

If the circuit fails to perform properly and the batteries are found to be good, a step-by-step procedure should be followed to discover the fault.

First check the current supply wave form at the current output terminals. This should be a 100 cps square wave about 1.3 volts amplitude. Sritch to the 1 ohm range so that oscilloscope loading will not affect the wave form. If the desired wave form is not present, check the generator circuit stage by stage. $Q 1$ and $Q 2$ are connected as a multivibrator. Q3 and Q4 are cascaded emmitter followers which develop the output current drive.

If the current supply works properly, check the voltage amplifier. First compare observed operating potentials with those given in the Voltage Diagram in this section. When operating points are all correct, the amplifier may be checked stage by stage for amplification. Note that V5 is used to supply current to the meter, and therefore has a voltage gain of only about one.

The voltage required at the junction between Cll5 and the meter diodes for full scale deflection is approximately 0.75 volt RMS.

The Voltage Diagram, DR 12256-C, Circuit Schematic, DR 12189-D and parts list are included at the back of the manual.

SECTION 6. REPLACEABLE PARTS
```

6-1. REPLACEABLE PARTS LIST. The Replaceable Parts List describes the components of the Model 502 and its accessories. The List gives the circuit designation, the part description, a suggested manufacturer, the manufacturer's part number and the Keithley Part Number. The name and address of the manufacturers listed in the "Mfg. Code" column are contained in Table 2.

## 6-2. HOW TO ORDER PARTS.

a. For parts orders, include the instrument's model and serial number, the Keithley Part Number, the circuit designation and a description of the part. All structural parts and those parts coded for Keithley manufacture (80164) must be ordered from Keithley Instruments, Inc. In ordering a part not listed in the Replaceable Parts List, completely describe the part, its function and its location.
b. Order parts through your nearest Keithley distributor or the Sales Service Department, Keithley Instruments, Inc.

TABLE 2. Code List of Suggested Manufacturers. (Based on Federal Supply Code for Manufacturers, Cataloging Handbook H4-1.)

## MODEL 502 VOLTAGE CHART

TUBE AND TRANSISTOR VOLTAGES ARE MEASURED FROM TUEE PIN TO CHABSIS GROUND WITH CONTROLS SET AS FOLLOWS: RANGE 'GWITCH AT' BATTERY TEST'

RANGE ' $O W I T C H$ AT BATTERY TE'
READ SHORT' SWITCH AT'SHORT'
ALL READINGS ARE APPROXIMATE AND ARE TAKEN WITH AN II MEGDHM INPUT RESISTANCE VTVM.

Keithley Instruments, Inc./28775 Aurora Road/Cleveland, Ohio 44139/(216) 248-0400/Telex: 98-5469
Keithley Instruments GmbH/Herglh ofstrasse 5/D-8000 Munchen 70/(089) 714-40-65/Telex: 5212160
