

## WARRANTY

We warrant each of our products to be free from defects in material and workmanship. Our obligation under this warranty is to repair or replace any instrument or part thereof which, within a year after shipment, proves defective upon examination. We will pay domestic surface freight costs.
To exercise this warranty, call your local field representative or the Cleveland factory, DDD 216-248-0400. You will be given assistance and shipping instructions.

## REPAIRS AND RECALIBRATION

Keithley Instruments maintains a complete repair service and standards laboratory in Cleveland, and has an authorized field repair facility in Los Angeles and in all countries outside the United States having Keithley field representatives.

To insure prompt repair or recalibration service, please contact your local field representative or the plant directly before returning the instrument.
Estimates for repairs, normal recalibrations, and calibrations traceable to the National Bureau of Standards are available upon request.

## TABLE OF CONTENTS

* Yellow Change Notice sheet is included only for instrument modifications affecting the Instruction Manual.

## SECTION 1. INTRODUCTION

## 1-1. GENERAL.

a. The Model 149 Mili-Microvoltmeter is a stable, versatile instrument for measuring low-level dc signals. It functions as a voltmeter from 100 nanovolts full scale to 100 millivolts. It also operates as a dc amplifier with gains up to $10{ }^{8}$ for driving recorders.
b. The low noise level of the Model 149 , together with its long-term stability, makes it ideal for many measurements requiring extreme power sensitivity.
c. Typical applications include measuring the output from strain gages, thermopiles, thermocouples, bolometers, phototubes, ionization chambers, scintillation counters, and barrier layer cells. Other applications are found in cell studies, measurement of electrochemical potentials, electrolytic corrosion studies, molecular weight analysis and Hall effect studies.
d. In addition to its use as a direct indicator of minute potentials and currents, the Model 149 may also be used as a null detector in Wheatstone or Mueller bridges.
e. An important feature of the instrument is zero suppression up to 100 times full scale in place of the usual more limited meter zero. This permits measurements of small signals in the presence of large thermal emf's or other masking de signals.

FIGURE 1. Keithley Instruments Model 149 Milli-Microvoltmeter.

## 1-2. SPECIFICATIONS.

RANGE: 0.1 microvolt ( $10 \times 10^{-8}$ volt) full scale to 100 millivolts on zero-center meter. 13 overlapping ranges in $1 x$ and $3 x$ steps.

ACCURACY: $\pm 2 \%$ of full scale on all ranges exclusive of noise and drift.
ZERO DRIFT: Less than 10 nanovolts per hour or less than 30 nanovolts in any 8 -hour period after approximately 2 -hour warm-up with reasonably constant ambient temperature. Long-term drift is non-cumulative.

INPUT NOISE (with input shorted): Less than 0.6 nanovolt rms (3 nanovolts peak-to-peak) on most sensitive range.

INPUT CHARACIERISTICS:

| Range | Input Resistance Greater than, ohms | Maximum Source Resistance, ohms |
| :---: | :---: | :---: |
| $0.1 \mu \mathrm{~V}$ | 10 k | 100 |
| $0.3 \mu \mathrm{~V}$ | 30 k | 300 |
| $1.0 \mu \mathrm{v}$ | 100 k | 1 k |
| $3.0 \mu \mathrm{v}$ | 300 k | 3 k |
| $10.0 \mu \mathrm{v}$ | 1 M | 10 k |
| $30.0 \mu \mathrm{~V}$ | 3 M | 30 k |
| $100 \mu \mathrm{v}$ and above | 10 M | 30 k |

Note: ${ }^{1}$ Source resistances higher than the recommended maximum will increase noise and rise time.

LINE FREQUENCY REJECTION: Greater than 50:1 on the most sensitive range, (Ratio of impressed peak-to-peak line frequency voltage at input to indicated dc voltage.)

ISOLATION: Circuit ground to chassis ground: Approximately $10^{9}$ ohms shunted by $0.05 \mathrm{mi}-$ crofarad. Circuit ground may be floated up to $\pm 400$ volts with respect to chassis ground.

RISE TIME ( $10 \%$ to $90 \%$ ):
0.1 -microvolt Range: Less than 2 seconds when source resistance is less than $10 \%$ of maximum; 4 seconds using maximum source resistance.
$0.3-\mathrm{mic}$ covolt to $100-\mathrm{millivolt}$ Ranges: Less than 1 second when source resistance is
less than $10 \%$ of maximum; 2 seconds using maximum source resistance.
ZERO SUPPRESSION: Up to at least 1 millivolt on the microvolt ranges and up to at least 10 millivolts on the millivolt ranges. Stability is such that 100 times full scale may be suppressed.

RECORDER OUTPUT:
Output: $\pm 10$ volts dc at up to 5 milliamperes for full-scale meter deflection.

Resistance: Less than 10 ohms within the amplifier pass band.
Gain: $\frac{10 \text { volts }}{\text { Range setting in volts }}$

Noise: Input noise times gain plus modulation products.

Modulation Products: Less than $2 \%$ peak-to-peak of full scale with input shorted.
CONNECTORS: Input: Special connector. Front Output: Binding posts. Rear Output: Ampheno1 80-PC2F.

POWER: 105-125 or 210-250 volts, 60 cps, 50 watts. $50-\mathrm{cps}$ models available. DIMENSIONS, WEIGHT: 7 inches high x 19 inches wide x 13 inches deep; net weight, 24 pounds. ACCESSORIES SUPPLIED: Model 1501 Low Thermal Input Cable with alligator clips; mating output connector; length of low-thermal solder.*

[^0]
## SECTION 2- OPERATION

## A. OPERATING CONTROLS

The controls of the Model 149 are aimple and conveniently placed. Their functions are as follows:

ON-OFF switch is located to the right of the panel meter.

FUNCTION switch selects the function which is to be used: Millivolts, or microvolts.

RANGF switch selects the full scale multiplier of the function selected by the FUNCTION switch.

ZERO SUPPRESS controls consists of the ZERO RANGE switch which selects the coarse range of suppressing voltage in discreet steps and the ZERO SET potentiometer which gives continuously variable fine control including settings through zero.
B. PRELIMINARY SET-UP

Connect the instrument to the power line. Unless otherwise marked the unit may be used on 117 volt, 60 cps 11 ne . To convert to 220 -volt operation, refer to the MAINTBNANCE section. A three-wire line cord is furnished, which grounds the cabinet. If a three-wire receptacle is not available, use the two-pin adapter furnished, and ground the third lead to an external ground.

## Set controls as follows:

Function: Millivolts
Range: 100
Zero Suppress: OFF
Input: Short the input leada together.

## C. GENERAL PRECAUTIONS

1. Source Resistance - In Section 1 under the Input Resistance Specification, the maximum source resistance for use with each voltage range is specified. Reasonable operation is possible with source resistance up to ten times greater than those specified, however, the measurement will suffer from a considerable decrease in speed of response, and measuring accuracy. If the instrument is left completely open-circuited, the meter will generally drift off scale on any range.
2. Shielding - Since the instrument operates with a modulator frequency of 120 cps , it is not generally sensitive to 60 cps pickup unless it is large enough to overload the amplifier. The pickup may be a source of difficulty when using the amplifier with high impedances on the more sensitive voltage ranges. In these cases it is desirable to shield the leads and the sources as completely as possible. In some cases a simple low-pass filter at the input to eliminate frequencies of about 1 cps and above will be helpful. No use is made of an input filter in this instrument since any input series impedance due to the filter will increase the input noise and the thermal drift. When operating above ground, the case of the instrument must be grounded.
3. Determination of Excessive AC Ptckup - A terminal attached to the output of the AC amplifier at the point of the demodulator is provided at the rear of the instrument. It is labeled DEMOD. OUTPUT. If an inability to make consistent readings persists, it is possible to check for the presence of excessive pick-up by observing the wave-form at this point. With the input shorted the picture should be approximately as shown in figure 2. If excessive pickup is observed it will look as shown in figure 3. The circuit will operate reasonably well as long as the wave-form does not clip as shown in figure 4. At this point the operation will be erratic.

FIGURE 2

FTHURE 3

4. Thermal EMF - Extreme precautions have been taken in the input circuit to minimize thermal EMF's so the residual EMF is usually less than 0.5 uv . The material used in the input circuit is pure copper. Any other metal will generate a thermocouple potential. Lead solder is particularly troublesome. Where thermal EMF's are a problem, soldering should be done with the cadmium-tin solder supplied with the instrument.
5. Input Noise - The noise at the input is a function of input resistance and is approximately given by

$$
E=1.29 \times 10^{-10} \sqrt{\left(\mathrm{R}^{+} 10\right)}
$$

where $E$ is the RMS noise, and $R$ is the source resistance. It is assumed that the bandwidth of the instrument is about 1 cps and the temperature is $80^{\circ} \mathrm{F}$. If noise is observed, calculate the theoretical noise and compare results. Also bear in mind that only wire-wound resistors approach the ideal resistor. However, if Evanohm or Manganin resistors are used, a considerable thermal EMF of the resistor material against copper will be observed.
6. Checking the Zero Point - At low levels, spurious EMF's may be generated simply by contact between the input leads and the terminals under test. If possible, always leave the instrument connected and adjust the zero after establishing a zero reference in the apparatus under test. For example, in bridge measurements, disconnect the bridge exciting voltage; or with a phototube, shield the tube from light.
7. Overloads - The current applied to the input circuit should be less than one milliampere dc steady state, 10 milliamperes dc short-term. When the FUNCTION switch is on the MILLIVOLTS position, the off-scale impedance can be as low as 1000 ohms. On the MICROVOLTS position, it may approach one ohm.

## D. MEASURING VOLTAGE

1. Direct Voltage Measurements - Place the FUNCTION switch at MILLIVOLTS or MICROVOLTS as necessary for the measurement to be taken. Then turn the RANGE switch to more sensitive ranges until the meter gives a usable deflection.
2. Measuring Voltage Variations - To observe small variations in a large steady signal, first set the FUNCTION and RANGE switches as described in D 1. Then operate the ZERO SUPPRESS switch and potentiometer to reduce the meter deflection to zero. Increase the meter sensitivity with the range
switch. The stability of the suppression voltage is adequate for 100 x full scale suppression. Thus, if a thermocouple is suppling a signal of 10 millivolts to the Model 149 after suppressing the meter deflection to zero, the RANGE may set at 100 microvolts. If the 10 millivolt signal corresponds to a temperature of $250^{\circ} \mathrm{C}$ then after suppression variations of $2.5^{\circ} \mathrm{C}$ are seen full-scale.
3. Measuring Differential Voltages - When measurements are to be made in a circuit where the LOW connection is above ground potential, slide OUTPUT LINK from one of its posts. This disconnects the instrument circuit ground from chassis ground. DO NOT attempt to make such measurements where the side of the circuit being measured is more than 400 volts above external ground potential.

If a recorder is being used with the instrument in this arrangement, the recorder must not be grounded since the low side of the output is no longer being grounded.

The Keithley Model 370 Recorder is ideal for use with the Model 149 in recording operations. The Model 370 maximizes the performance of the Model 149 over the Milli-Microvoltmeter's entire range. The Model 370 can float -500 off ground.

## E. OTHER APPLICATIONS

1. Null Indicator - The Model 149 makes an extremely sensitive null indicator which may be used in a wheatstone or Mueller Bridge.

If the bridge is arranged so than one terminal of the detector is grounded, the Model 149 may be used as described in D 1. If the detector must be used floating, remove the DISCONNECT LINK at the rear and observe the same precautions as in $D 3$.

## SECTION 3 - CIRCUIT DESCRIPTION

The Model 149 is basically a narrow-band chopper amplifier employing negative feedback to stabilize the gain and increase the input impedance.

## A. Input Circuit

Zero Stability: The effect of thermal EMF's generated in the input circuitry is reduced to nearly the vanishing point by the use of only copper in the input circuit. All solder points are made with a low thermal cadmium-tin solder. The chopper and chopper transformer employ copper leads. All switching in the input circuit is accomplished with copper switch. Critical resistors in the input circuit are wound of copper wire. The input connector has solid copper springloaded contacts.

The input voltage is applied to the moving arm of a 120 cps mechanical chopper. The feedback voltage is connected to the primary center tap of the input transformer. Thus, the difference voltage is applied first across one half of the primary and then, with phase reversal, to the other half. This full wave error signal is stepped up 90 to 1 by the input transformer and applied to the grid of V1, a 6084 Law-noise pentode.
B. AC Amplifier

In parallel with the plate load resistor of $V 1$ is a relatively high $Q, 120 \mathrm{cps}$ resonant circuit which narrows the bandwidth and reduces spurious signals.

V2 and V3, EF86 pentodes, further amplify the chopper error signal which is then demodulated synchronously by silicon diodes Dl through D4 .

To obtain the 120 cps demodulator driving signal, use is made of the ripple frequency from a bridge rectifier circuit operating from the line voitage. The ripple is used in the primary of the demodulator driver transformer.
C. DC Amplifier

The demodulated signal is applied to the grid of V4. V4, V5, and V6 form the dc amplifier and output cathode follower which add further forward gain to the system and supply output power. Feedback around V4, V5 and V6 multiplies the effective capacitance of demodulator filter capacitor C113 by about 1000. This yields the large equivalent capacitance necessary to smooth the demodulated error signal. Because of the feedback, spurious noise in the de stages outside the pass band of the whole amplifier are effectively degenerated.

## D. Zero Suppression

A low-current $\pm 10$ volt supply is derived from the main dc supplies using lo-volt zener diodes. Potentiometer R154, may be set at any voltage from -10 to +10 volts, this voltage is applied through appropriate dropping resistors to the feedback point to achieve zero suppression. The potentiometer is the front panel control marked ZERO SUPPRESSS, while switch S3, which determines the portion feedback, is Labeled ZERO SUPPRESS, OFF-INCREASE.
E. Other Controls

Two controls are set at the factory and should require only infrequent attention by the user.

R118 is an internal control marked DC AMP BAL. It is used to zero the DC amplifier, i.e., to set the output voltage to zero when the demodulator output is zero. This is not very critical since an unbalance will simply be fed back to the input to produce a small error signal to correct itself. R127 is marked CAL. This is the variable portion of the meter multiplier resistance to allow for meter-to-meter sensitivity differences.
F. Power Supply

A standard half-wave rectifier followed by an $R-C$ filter is used to supply unregulated $B+$ and $B$ - to the output cathode follower.

The unregulated $B-$ is regulated to -150 volts in V7, OA2, and is used for the negative returns for the dc amplifier.

Unregulated $B+$ is fed to the plate of V8, $12 B 4 A$, the series tube in a 225 volt electronic regulator. The output voltage from this regulator is divided by R510 and R511 and compared to reference tube V9, a 5651. The difference signal is amplified by cascade amplifier V10, a 12AX7, and applied to the grid-cathode circuit of the series tube. This regulated 225 volts supplies $B+$ directly to the dc amplifier, through a decoupling filter (RI76, Cllo) to the second and third ac amplifier stages, and through another decoupling filter (R103, C104) to the first ac amplifier stage.

Regulated $B+$ and $B-$ also supply currents to the 10 volt zener diodes which are used for zero suppression. This gives two-stage regulation for these very critical voltages.

Zener Diode D 112 regulates the filament voltage of $V 1$ to reduce 1 ine transient effects.

## SECTION 4 - MAINIENANCE

Except for occasional tube or chopper replacement, very little maintenance is required by the Model 149 . Components are operated well below rating and solid state devices are employed where possible to achieve long, trouble-free service.

Certain portions of the input circuit are wired using chopper wire and special cadmium-tin solder. These special joints are painted red. If, for any reason, these joints must be unsoldered or re-soldered, USE ONLY CADMIUM-TIN SOLDER AND A COPPER-IIPPED SOLDERING IRON WHICH HAS NEVER BEBN USED WIMH ORDINARY IEAD IIN SOLDER. A small spool of cadmium-tin solder is supplied with each instrument.

What may seem to be circuit failure in the millimicrovoltmeter is quite often found to be an unususl condition in the entire test set-up. Therefore, before trouble-shooting the instrument, check to see whether it operates correctly with:

1. All other circuitry disconnected.
2. Input shorted (with copper leads).
3. Power line voltage and frequency correct.

If the difficulty persists, the following systematic procedure may be employed to determine the fault.

TROUBLE-SHOOTING
Reference is made to the Schematic Dlagram 13621D, and the Voltage-Resistance Diagram enclosed at the rear of the manual.

To begin troublemshooting, short the input terminals, strap $G$ to IO with the link provided, and switch ZRRO SUPPRESS, OFF-INCREASE to OFF. A Zero offset of 0.1 to 0.4 microvolt is normal.

## EXCESSIVE OUTPUT FOISE (INFUT THEMTNAIS SHORIWD)

Because of the very low signal levels involved, noise in the ac amplifier is difficult to trace except by the substitution method. Most likely noise sources are VI and the chopper. If noise persists after replacing the chopper, it is being generated in the dc amplifier or power supply. A stage-by-stage search should reveal the source. Very often the noise is generated by Rlo2, low noise metal film resistor. Replace only with the equivalent resistor. Wire-wound resistors tend to introduce inductive pickop.

To replace the chopper, unplug the cap at the top. From the bottom of the Model 149, remove the plate covering the area around the chopper base. Unsolder the chopper leads. Clean out the lead at the input connector; tag the terminal for a correct connection later. Unscrew the chopper mounting screws and lift out the chopper from the top.

Insert the new chopper from the top, putting the wire leads through the holes. For convenience, place the No. 2 lead nearest the Model 149 side as shown in Figure 5. From the bottom, secure the chopper with four No. $4-40$ NC-2 screws. Put approximately $3 \frac{1}{2}$ in. of teflon tubing over lead No. 2 and $2 \frac{1}{4}$ in. over the other two leads.

Solder lead No. 2 to the input connector. Insert a shorting bar into the input connector to push out the leads enough to facilitate working on the connection.

NoTE: Use soldering iron with a new solid copper tip and low-thermal cadmium solder for all solder connections painted red. This solder is supplied with the Model 149. Make sure of good electrical and mechanical connections.

Connect lead No. 1 to the red lead. of transformer TR37; connect lead No. 3 to the blue lead of transformer TR37. Make loops at the lead ends, interlock the loops, and solder Do not cross or twist the leads. Slide the tubing over the connections.

FIGURE 5. Chopper Replacement. View is from the bottom of Model 149.

Twist shield lead V around chopper lead No. 2 as shown in Figure 5. Make sure the end of the shield lead is free of all contact. Replace the plate over the chopper base. Plug in the cap at the top of the chopper.

OUTPUT NOT ZERR (WITHIN 0.5 MICROVOLAS) WITH INPUT IERRMTNATS SHORTED
Be sure the ZERO SUPPRRSS is set to OFF. Short the de amplifier input grid, pin 7 of V4, to ground. Use the DC AMP BAL control to set the output to zero. The control will become very "scratchy" but the adjustment is possible. If this cannot be done, the dc amplifier or power supply are at fault. If it can be set to zero, the trouble may be in the ac amplifier or demodulator circuit.
a. Power Supply - B+ should be about +225 on pin 1 of V8, and B- should be -150 on pins 2, 4 or 7 of V7. If V7 is not firing, correct the fault in the unregulated B-. If +225 is not present, check for unregulated B+ (about 340 volts) at the plate pin 9 of V8. If the unregulated $B+$ is all right, check the tube pin voltages of V8, V9, and V. 10 to locate the faulty tube or part.
b. AC Anplifier - Remove the output tube (v6) and clip pin 1 of the output connector to ground. Place the FUNCTION switch on MIIJIVOLIS, and turn the ZERO SET and ZERR RANGE controls full clockwise. This puts a large de error
signal across the chopper and input transformer. Use an oscilloscope to check for the presence of 120 cps at the primary of the input transformers (the two outside terminals on the chopper terminal block). Absence of signal means chopper failure (or much less likely, a shorted or open input transformer). Listen for audible chopper action and check chopper drive, if necessary.

If the 120 cps signal is present, check stage-by-stage throughout the ac amplifier, reducing the input signal as desired by backing off the ZERO RANGE and/or ZRRO SET controls, until the failure is discovered.
d. Demodulator Circuit - Check for presence of about 80 volts RMS at the secondary of the demodulator transformer (at the ends of R113 and R114).

The tests outlined above will not suffice to pin-point every fault which may exist. They should, however, lead to the correction of common failures. In the event that troubles cannot be corrected by these means, or the user finds it more expedient, the unit may be returned to the factory for repair and recalibration at a nominal cost.

## 220-VOLI OPERATION

For 220 -volt operation the power transformer primary connections mast be changed. The jumpers connecting black and black-white together and blue and blue-white should be removed. The blue and black-white leads should be tied together. Replace the 1.5 -ampere fuse (Keithley Part No. FU-8) with a 0.75 -ampere fuse (Keithley Part No. FU-I4).

## SECTION 5. REPLACEABLE PARTS

5-1. REPLACEABLE PARTS LIST. The Replaceable Parts List describes the components of the Model 149 and its accessories. The List gives the circuit designation, the part description, a suggested manufacturer, the manufacturer's part number and the Keithley Part Number. The name and address of the manufacturers listed in the "Mfg. Code" column are contained in Table 3.

## 5-2. HOW TO ORDER PARTS.

a. For parts orders, include the instrument's model and serial number, the Keithley Part Number, the circuit designation and a description of the part. All structural parts and those parts coded for Keithley manufacture (80164) must be ordered from Keithley Instruments, Inc. In ordering a part not listed in the Replaceable Parts List, completely describe the part, its function and its location.
b. Order parts through your nearest Keithley distributor or the Sales Service Department, Keithley Instruments, Inc.

December 6. 1967
MODEL 149 MILLI-MICROVOLTMETER
Page 1-2. INPUT CHARACTERISTICS: Change the last value in the - Maximum Source Resistance, ohms - column to 30 k .

Change the RISE TIME Specification to:
RISE TIME ( $10 \%$ to $90 \%$ ):
0.1 - microvolt Range: Less than 2 seconds when source resistance is less than $10 \%$ of maximum; 4 seconds using maximum source resistance.
0.3 - microvolt to 100 - millivolt Ranges: Less than 1 second when source resistance is less than $10 \%$ of maximum; 2 seconds using maximum source resistance.
